Abstract

Deep denoiser, the deep network for denoising, has been the focus of the recent development on image denoising. In the last few years, there is an increasing interest on developing unsupervised deep denoisers which only call unorganized noisy images without ground truth for training. Nevertheless, the performance of these unsupervised deep denoisers is not competitive to their supervised counterparts. Aiming at developing a more powerful unsupervised deep denoiser, this paper proposed a data augmentation technique, called recorrupted-to-recorrupted (R2R), to address the overfitting caused by the absence of truth images. For each noisy image, we showed that the cost function defined on the noisy/noisy image pairs constructed by the R2R method is statistically equivalent to its supervised counterpart defined on the noisy/truth image pairs. Extensive experiments showed that the proposed R2R method noticeably outperformed existing unsupervised deep denoisers, and is competitive to representative supervised deep denoisers.

1. Introduction

Image denoising is one fundamental problem in image processing which receives an enduring interest in last decades. It aims at removing random noise from the input images to improve their signal-to-noise-ratios (SNRs). Image denoising is not only an important problem itself but also serves as a basic module in many image recovery methods. A noisy image is usually formulated as

\[ y = x + n, \]  

where \( y \) denotes the noisy image, \( x \) the noise-free image for recovery, and \( n \) measurement noise. The noise \( n \) is often assumed to be the instance drawn from some distribution.

In recent years, deep learning is the main driving force in the development of image denoisers. A majority of existing deep-learning-based denoising methods (e.g. [31, 36, 37]) are supervised, which learn the mapping from noisy input to its clean counterpart by training a deep neural network (DNN) on many clean/noisy image pairs. However, in order to have a trained model that generalizes well, a great amount of such noisy/clean image pairs are needed to sufficiently cover the variations on image content and measurement noise. Fulfilling such a demanding requirement on training samples may be costly and sometimes challenging. For example, it is non-trivial to collect real-world noisy/clean image pairs; see e.g. [25, 33, 3]. For scientific images and medical images, the task is more challenging.

Recently, it is receiving an increasing interest on relaxing the prerequisite of supervised learning on training samples. Lehtinen et al. [21] presented a weakly supervised method, the so-called Noise2Noise method, which directly trains the DNN between the pairs of two noisy images of the same scene. As the noise of such image pairs is independent, the expectation of the cost function of Noise2Noise is then the same as that of the supervised one defined on the noisy/truth image pairs. Extensive experiments showed that the proposed R2R method noticeably outperformed existing unsupervised deep denoisers, and is competitive to representative supervised deep denoisers.

• Data augmentation methods. Noise2Void [17] and Noise2Self [5] adopt the blind-spot strategy to avoid overfitting (convergence to identity map) when training a DNN to map a noisy image to itself, while Noiser2Noise [23] and Noise-as-Clean [32] add additional noise to the original noisy image to make image pairs which are then used to train the DNN.

• Regularized denoising DNN. The Stein’s Unbiased Risk Estimator (SURE) [29, 22] regularizes the DNN by penalizing the divergence of the prediction. Deep image prior [30] uses early-stopping to avoid the overfitting. In Self2Self [26], a dropout-based training/testing scheme is introduced to reduce the bias and variance of the prediction from the DNN trained on single noisy image.
1.1. Motivation

Despite the great progress in last few years, the performance of unsupervised learning methods for denoising is still not comparable to that of their supervised counterparts, e.g. DnCNN [36] trained on noisy/clean pairs or Noise2Noise trained on noisy/noisy pairs. Indeed, many of them cannot compete well against classical non-local denoising method such as BM3D [11]. So far, SURE [29] provided the state-of-the-art (SOTA) performance among dataset-based unsupervised denoiser, and Self2Self [26] provided the SOTA performance among single-image-based unsupervised denoiser. In summary,

- Unsupervised learning has its value in many real-world applications, since it remains useful when no ground-truth image is available.
- Most existing unsupervised learning methods have a noticeable performance gap to their supervised counterparts, especially for denoising real-world images.

This paper aims at developing an unsupervised learning method for denoising that works on a set of unorganized noisy images without truth images. The proposed method not only provides the SOTA performance among existing unsupervised learning methods, but also is very competitive to many supervised learning methods including DnCNN.

1.2. Main idea

Revisiting Noise2Noise. Before proceeding, we take a revisit to Noise2Noise, the first attempt that relaxes the requirement of supervised denoising methods on training dataset: from noisy/clean image pairs to noisy/noisy image pairs. It is shown in [21] that the performance of a denoising network trained on noisy/noisy image pairs is roughly the same as that trained on noisy/clean image pairs of the same scene. Mathematically speaking, in the setting of additive Gaussian white noise (AGWN), a pair of noisy images of the same scene can be expressed as

\[ \mathbf{y} = \mathbf{x} + \mathbf{n}, \quad \mathbf{n} \sim \mathcal{N}(0, \sigma_n^2 \mathbf{I}), \]

\[ \mathbf{y} = \mathbf{x} + \mathbf{n}', \quad \mathbf{n}' \sim \mathcal{N}(0, \sigma_n^2 \mathbf{I}). \]

Let \( \mathcal{F} \) denote the denoising DNN. Then, Noise2Noise trains the DNN by minimizing the squared-\( \ell_2 \) loss:

\[ \mathbb{E}_{\mathbf{n}, \mathbf{n}'} \{ \| \mathcal{F}_\theta (\mathbf{y}) - \mathbf{y}' \|^2_2 \}. \]  

(2)

Such a loss function is closely related to the one used in supervised learning:

\[ \mathbb{E}_{\mathbf{n}} \{ \| \mathcal{F}_\theta (\mathbf{y}) - \mathbf{x} \|^2_2 \}. \]  

(3)

Indeed, we have

\[ \mathbb{E}_{\mathbf{n}, \mathbf{n}'} \{ \| \mathcal{F}_\theta (\mathbf{y}) - \mathbf{y}' \|^2_2 \} = \mathbb{E}_{\mathbf{n}, \mathbf{n}'} \{ \| \mathcal{F}_\theta (\mathbf{y}) - \mathbf{x} - \mathbf{n}' \|^2_2 \} = \mathbb{E}_{\mathbf{n}, \mathbf{n}'} \{ \| \mathcal{F}_\theta (\mathbf{y}) - \mathbf{x} - 2(\mathbf{n}')^\top (\mathcal{F}_\theta (\mathbf{y}) - \mathbf{x}) + (\mathbf{n}')^\top \mathbf{n}' \} = \mathbb{E}_{\mathbf{n}, \mathbf{n}'} \{ \| \mathcal{F}_\theta (\mathbf{y}) - \mathbf{x} \|^2_2 \} - 2\mathbb{E}_{\mathbf{n}, \mathbf{n}'} \{ (\mathbf{n}')^\top \mathcal{F}_\theta (\mathbf{y}) \} + \text{const}. \]

As long as the noise \( \mathbf{n} \) and \( \mathbf{n}' \) are independent, which gives \( \mathbb{E}_{\mathbf{n}, \mathbf{n}'} \{ (\mathbf{n}')^\top \mathcal{F}_\theta (\mathbf{y}) \} = 0 \), the expectation of the loss function defined on \( (\mathbf{y}, \mathbf{y}') \) will be equivalent to the supervised one defined on \( (\mathbf{y}, \mathbf{x}) \) up to a constant. This is the reason why Noise2Noise can perform comparably to its supervised counterparts.

Re-corrupting both the input and target image for training on unorganized noisy images. Different from the dataset required by Noise2Noise, we only assume the availability of a set of unorganized noisy images without pairwise correspondence. In order to achieve comparable performance to Noise2Noise, the question is then about how to construct a pair of noisy images \( (\tilde{\mathbf{y}}, \mathbf{y}) \) with independent noise from a single noisy image \( \mathbf{y} = \mathbf{x} + \mathbf{n} \) such that

\[ \mathbb{E} \{ \| \mathcal{F}_\theta (\tilde{\mathbf{y}}) - \mathbf{y} \|^2_2 \} = \mathbb{E} \{ \| \mathcal{F}_\theta (\tilde{\mathbf{y}}) - \mathbf{x} \|^2_2 \} + \text{const}. \]

In the setting of AWGN: \( \mathbf{n} \sim \mathcal{N}(0, \sigma_n^2 \mathbf{I}) \), our answer to the above question is to re-corrupt the noisy image \( \mathbf{y} \) as follows:

\[ \tilde{\mathbf{y}} = \mathbf{y} + D^\top \mathbf{z}, \quad \mathbf{y} = \mathbf{y} - D^{-1} \mathbf{z}, \quad \mathbf{z} \sim \mathcal{N}(0, \sigma_n^2 \mathbf{I}), \]  

(4)

where \( D \) can be any invertible matrix. We showed in Corollary 2 (Section 3) that the noise in \( \tilde{\mathbf{y}} \) and \( \mathbf{y} \) are independent from each other, and thus the squared-\( \ell_2 \) loss function trained on the image pair \( (\tilde{\mathbf{y}}, \mathbf{y}) \) satisfies

\[ \mathbb{E}_{\mathbf{n}, \mathbf{z}} \{ \| \mathcal{F}_\theta (\tilde{\mathbf{y}}) - \mathbf{y} \|^2_2 \} = \mathbb{E}_{\mathbf{n}} \{ \| \mathcal{F}_\theta (\mathbf{x} + \mathbf{n}) - \mathbf{x} \|^2_2 \} + \text{const}, \]  

(5)

where \( \mathbf{n} = \mathbf{n} + D^\top \mathbf{z} \). Consider a dataset of un-organized noisy images

\[ \mathbf{y}^k = \mathbf{x}^k + \mathbf{n}^k, \quad \mathbf{x}^k \sim \mathcal{X}, \mathbf{n}^k \sim \mathcal{N}(0, \sigma_n^2 \mathbf{I}), \quad k \in \mathbb{N}. \]

The cost function defined on the pairs \( \{ (\mathbf{y}^k, \tilde{\mathbf{y}}^k) \}_{k \in \mathbb{N}} \) constructed by (4) is then equivalent to the following cost function:

\[ \mathbb{E}_{\mathbf{x}, \mathbf{n}} \{ \| \mathcal{F}_\theta (\mathbf{x} + \mathbf{n}) - \mathbf{x} \|^2_2 \} + \text{const}, \]

i.e., the one used in the supervised learning on a set of noisy/truth image pairs \( \{ (\mathbf{x}^k + \mathbf{n}, \mathbf{x}^k) \}_{k \in \mathbb{N}} \).

Discussion. From (5), it can be seen that the proposed scheme (4) of the image pair \( (\tilde{\mathbf{y}}, \mathbf{y}) \) leads to a loss function in the same form as that of Noise2Noise. Therefore, the network trained using the proposed scheme can be expected to have comparable performance to those supervised learning methods. Through this paper, the training scheme (5)
built on the construction scheme of image pair (4) is called Recorrupted-to-Recorrupted, abbreviated as R2R.

Moreover, the proposed R2R scheme also works for the noise which is signal-dependent. Suppose the noise follows a normal distribution \( \mathcal{N}(0, \Sigma_x) \) with the \( x \)-dependent co-variance matrix \( \Sigma_x \). Then, one only needs to modify the recorruption scheme as follows:

\[
\hat{y} = y + D^\top z, \quad \tilde{y} = y - D^{-1}z, \quad z \sim \mathcal{N}(0, \Sigma_x).
\]

The modified scheme above still leads to the same result as (5); See Section 3 for more details.

1.3. Contributions

In this paper, we proposed an unsupervised deep learning method for image denoising, named as R2R, which is trained on a dataset of un-organized noisy images, without truth or pair-wise correspondence. The contributions are summarized as follows:

- With rigorous mathematical treatment, this paper presented a so-called R2R unsupervised learning technique for image denoising, which is statistically equivalent to the supervised learning on noisy/clean image pairs.
- In comparison to other unsupervised learning methods for denoising, the proposed R2R is simple and flexible. It can be trained on external training samples or directly trained on noisy images for processing.
- Extensive experiments on synthetic noisy images show that the proposed R2R method performs better than all compared non-learning and unsupervised learning methods, and is comparable to representative supervised denoisers. For denoising real-world images, it is also very competitive to the top performers among the non-learning and unsupervised methods.

2. Related Work

There is abundant literature on image denoising, and we only focus on the most related ones.

**Non-learning image denoisers based on image priors.** In the past, many image denoisers have been proposed by imposing certain pre-defined image priors on clean images. Some widely-used image priors include: 1) Sparsity of image gradients, which leads to \( \ell_p \)-norm penalization methods, e.g. [3, 28]; 2) Similarity of image patches, which induces non-local methods, e.g. BM3D [11] and WNMM [12], or rank-based regularization such as [14].

**Supervised learning on noisy/truth image pairs.** Supervised deep learning has been a prominent tool for image denoising, which trains denoising DNNs on many noisy/truth image pairs, e.g. [36, 37, 20, 13, 15, 4, 35, 27]. The DNNs are trained to map noisy images to their clean counterparts. DnCNN [36], which uses a residual convolutional DNN for training, is one widely-used method for benchmarking deep image denoisers. Instead of using noisy/truth image pairs, the Noise2Noise (N2N) method [21] is weakly supervised that trains the DNN on pairs of independent noisy images of the same scene.

**Unsupervised learning on unpaired noisy images.** Without noisy/truth image pairs, one approach is to use generative adversarial network (GAN) to generate these pairs from unpaired data for training, e.g. [10, 7]. Another type of method directly trains the DNN on noisy data, and the focus is on how to avoid overfitting which sees the DNN convergence to the identity map. A SURE-based method [29] regularizes the DNN by penalizing the divergence of the prediction. Some other methods propose augmentation schemes to avoid overfitting and our R2R method falls into this category. In the following, we will review most related data augmentation methods.

Noise2Void (N2V) [17] and Noise2Self (N2S) [5] are based on the blind-spot strategy that randomly drops some pixels of the input and predicts them using their remaining neighbours. Laine et al. [18] proposes a specific blind-spot architecture that excludes the center pixel in its receptive field. The blind-spot technique can be conceptually interpreted as recorrupting the noisy sample by multiplicative Bernoulli noise. The issue is that a lot of information is discarded when discarding image pixels. In contrast, the proposed R2R keeps all image pixels. It is equivalent to train the DNN in a supervised manner with a only slightly higher noise level (e.g. \( D = \frac{1}{2}I \) in (4)). As a result, the R2R can be trained with better performance.

Given the noisy image \( y \), Noisier2Noise and Noisy-as-Clean use a noiser image as input, which is synthesized by recorrupting \( y \) with the noise \( z \), and then the DNN is trained over the pair \((y + \alpha z, y)\):

\[
\min_{\theta} \mathbb{E}_{y,z} \left\| F_\theta (y + \alpha z) - y \right\|^2_2. \tag{6}
\]

The connection between the loss function defined above to the supervised one is not clear. In comparison, taking \( D = \alpha I \) in (4), the R2R trains the DNN on \((y + \alpha z, y - z/\alpha)\):

\[
\min_{\theta} \mathbb{E}_{y,z} \left\| F_\theta (y + \alpha z) - (y - z/\alpha) \right\|^2_2, \tag{7}
\]

which rigorously showed its statistical connection to supervised learning. Indeed, the denoiser obtained by minimizing (6) is \( E(y|\tilde{y}) \) (\( \tilde{y} = y + \alpha z \)). To reduce noise effect further, Noisier2Noise runs a post-process for correction:

\[
\alpha^{-2}(1 + \alpha^2)E(y|\tilde{y}) - z).
\]

In contrast, our R2R obtains the ideal denoiser \( E(x|\tilde{y}) \) directly owing to the equivalence to the supervised learning.

Partially-linear denoiser [16] considered training a denoiser over the image pairs similar to our R2R method, and
showed its connection to supervised linear denoisers. As a denoising DNN is typically non-linear, they proposed to penalize the non-linear structure of the DNN to approximate its supervised counterpart well. A two-stage training procedure is then developed to learn such a denoiser with special structure. In comparison, the proposed cost function in our R2R method can use standard optimization procedure to train the network.

Self-supervised learning on single noisy image. In the past, there have been extensive studies on sparsity-driven un-supervised learning for denoising, e.g., The KSVD method for dictionary learning [2] and data-driven wavelet frames [6]. Recently, there are also some works that train the network only on the target image itself, without calling any external training samples. The deep image prior (DIP) [30] uses early stopping to avoid overfitting, as it is observed that regular image patterns can be learned prior to random noise during the training. The Self2Self (S2S) method [26] adopts a dropout-based ensemble technique to handle the overfitting, which has the SOTA performance among existing single-image-based methods.

3. Main body

Recall that a noisy image \( y \) and its noise-free counterpart \( x \) is related by

\[
y = x + n,
\]

where \( n \) denotes the random noise and follows the normal distribution \( \mathcal{N}(0, \Sigma_x) \). Typical supervised learning methods train the DNNs by

\[
\min_{\theta} \mathbb{E}_{x,y} L(\theta(y), x),
\]

where \( L(\cdot, \cdot) \) denotes some loss function and the squared \( \ell_2 \)-norm loss is used in the following. Without the access to clean images, simply replacing \( x \) in (8) with \( y \)

\[
\min_{\theta} \mathbb{E}_{y} \| \theta(y) - y \|_2^2,
\]

will yields a trivial identity solution, i.e., the DNN does not remove any noise but outputs the noisy image itself.

Instead, for each noisy sample \( y \), our R2R training generates paired images \( \{ (\hat{y}, \tilde{y}) \} \) as follows:

\[
\hat{y} = y + Az, \quad \tilde{y} = y - Bz,
\]

where \( A, B \) satisfies \( AB^\top = \Sigma_x \) and \( z \) is sampled from standard normal distribution \( \mathcal{N}(0, I) \). Then we train the DNN over \( (\hat{y}, \tilde{y}) \) by

\[
\min_{\theta} L(\theta; A, B) := \mathbb{E}_{y, z} \| \theta(y + Az) - (y - Bz) \|_2^2.
\]

Denote \( \hat{n} = n + Az \) and \( \tilde{n} = n - Bz \). It can be calculated that the covariance of \( \hat{n} \) and \( \tilde{n} \) is zero. Since they follow Gaussian distribution jointly, it yields that they are independent. Consequently, we have the following theorem regarding the loss function \( L(\theta; A, B) \) defined in (11).

**Theorem 1.** Suppose \( y = x + n \) and \( n \) follows the normal distribution \( \mathcal{N}(0, \Sigma_x) \). Define a pair of images \( (\hat{y}, \tilde{y}) \) by (10), where \( z \) is independent from \( n \). Then with the condition \( AB^\top = \Sigma_x \), it holds that

\[
L(\theta; A, B) = \tilde{L}(\theta; A) + \text{const},
\]

where \( \tilde{L}(\theta; A) \) is the supervised loss

\[
\tilde{L}(\theta; A) := \mathbb{E}_{x,y,z} \| \theta(y + Az) - x \|_2^2.
\]

**Proof.** See the supplemental material file for the proof. \( \Box \)

As an extension, we have the following corollary derived from Theorem 1.

**Corollary 2.** Suppose \( y = x + n \) and \( n \sim \mathcal{N}(0, \Sigma_x) \). The paired images \( (\hat{y}, \tilde{y}) \) are generated by

\[
\hat{y} = y + D^\top z, \quad \tilde{y} = y - D^{-1}z,
\]

where \( z \) draws from \( \mathcal{N}(0, \Sigma_x) \) and is independent of \( n \). Then it holds that

\[
\mathbb{E}_{y,z} \| \theta(y + Az) - \tilde{y} \|_2^2 = \mathbb{E}_{y,z} \| \theta(y + Az) - x \|_2^2 + \text{const}.
\]

Theorem 1 implies that our R2R training is equivalent to training a denoiser over paired noisy/clean images \( \{ (y + Az, x) \} \) in a supervised way. To test on the target noisy image \( u \), we feed \( u + Az \) into the trained DNN such that the statistics of the inputs are consistent during training and testing. Let \( \theta^* \) be the learned DNN parameter. The following scheme is used for prediction

\[
u^* = \int \theta^* (u + Az) \Phi_1(z) dz \approx \sum_{j=1}^{T} \theta^*(u + Az^j),
\]

where \( \{ z^j \}_{j=1}^{T} \) are independent samples from \( \mathcal{N}(0, I) \). The Monte Carlo approximation is used to approximate the integration. The averaging of multiple forward processes is to reduce the effect of recorruption on the input image. However, if the DNN is trained over a sufficiently wide range of noise levels, the obtained R2R denoiser can also work well for the original noise level. In this case, we compute \( \theta^*(u) \) directly to denoise the test image.

4. Experiments

In this section, we evaluate our proposed R2R training on AWGN denoising and real-world image denoising. More details can be found in the supplementary materials.
Our R2R training is independent of the network architectures. In our experiments, we use the same architecture as that of DnCNN [36], a baseline denoising DNN in the study of deep denoisers. The results of the compared methods are cited from the literature directly if possible. Otherwise, we use the pre-trained models or the codes provided by the authors to obtain the results. If none is available, e.g. Noisier2noise [23], we strictly follow the instructions of the paper to implement it by ourselves, and make efforts to optimize its performance.

Remark 3. In the comparison, the best performer is emphasized by bold, and the second best is colored in blue.

4.1. Experiments on AWGN denoising

In this section, we test the denoising performance on the gray scale version of the BSD68 dataset which is corrupted by AGWN of two noise levels $\sigma = 25, 50$. The compared dataset-based learning methods are retrained on the benchmark denoising dataset BSD400 which contains 400 gray scale images of size $180 \times 180$. Noisy versions of all the images are generated by adding zero-mean white Gaussian noise with specific noise levels. For unsupervised methods, including N2V [17], N2S[5], SURE [29], Laine et al. [18], Nr2N [23] and our R2R, only noisy images are provided for training. For N2N [21], one more noisy version of each training image is generated. During training, the patches of size $40 \times 40$ are extracted from the training images and augmented by rotation, flipping and mirroring. For our method, a DnCNN network with $17$ convolution layers is trained for $50$ epochs with batch size $128$. The initial learning rate is $10^{-3}$ and halves after $30$ epochs. We generate our R2R image pairs for training by (14), where $D = \alpha I$ and $D^{-1} = I/\alpha$ with $\alpha = 0.5$. For prediction, we use the scheme (16) with $T = 50$.

See Tab. 1 for quantitative comparison of different methods on the testing dataset and Fig. 1 for visual comparison of some results. It can be seen that among all non-learning methods and unsupervised methods, the proposed R2R is the best performer in terms of both PSNR and SSIM. It is surprising to see that our method also outperformed N2N, which is weakly supervised on the noisy/noisy image pairs. On plausible cause might be that N2N can only utilize the provided noisy pairs while our method can generate multiple instances of image pairs from single noisy image, which makes our R2R generalize better. In comparison with representative supervised learning method DnCNN, the performance gap between our method and it is very small, less than $0.1$dB in PSNR. That is, our proposed unsupervised method R2R is indeed comparable to its supervised counterpart, i.e. DnCNN.

4.2. Experiments on Real-Word Image Denoising

We test the performance of different methods on four real-world image datasets, i.e. CC [24], PolyU [33], SIDD Validation and SIDD Benchmark [1]. For CC, PolyU and SIDD Validation, ground truth images are provided. For SIDD Benchmark, the results are evaluated by submitting the denoised images to the project website.

The images in these datasets are captured by different cameras from different scenes and cropped to small image blocks for processing. There are $15$ and $100$ images of size $512 \times 512$ in the CC and PolyU dataset respectively. For both the SIDD Validation and Benchmark, images of $40$ scenes are captured, each of which are cropped into $32$ blocks of size $256 \times 256$, resulting in totally $1024$ image blocks in the dataset.

SIDD dataset with unorganized noisy images for training. For SIDD, there is a training dataset with raw format available. The camera image processing pipeline is also available to convert the image in raw format to sRGB format.

For noisy raw-RGB images in the training dataset, the noisy level function (NLF) is reported, which models the noise as a heteroscedastic signal dependent Gaussian variable with its variance proportional to the image intensity:

$$
\Sigma_x = \text{diag}(\beta_1 x + \beta_2),
$$

where $\beta_1$ is the signal-dependent multiplicative component of the noise (the Poisson or shot noise), and $\beta_2$ is the independent additive Gaussian component of the noise.

We use the provided NLF to generate independent noisy raw-RGB image pairs by the scheme (14) with $D = 2I$, and $D^{-1} = I/2$, without calling the estimated clean images in the SIDD training dataset. These raw-RGB image pairs are then rendered to sRGB images using the provided camera image processing pipeline procedure for the following training of a sRGB-to-sRGB denoising DNN. Note that neither gamma correction nor tone mapping are called to generate the sRGB images provided in SIDD Validation and Benchmark dataset, and the same for our generated R2R sRGB noisy image pairs. As a result, the mean of image noise remains zero after being converted from raw-RGB space to sRGB space, and our method is still applicable.

320 noisy images in SIDD-Medium Dataset and a DnCNN with $20$ convolution layers are used for our method. At each iteration, $32$ pairs of image patches of size $128 \times 128$ from the dataset are extracted for training. The number of iteration is $5 \times 10^5$ and the learning rate is $5 \times 10^{-5}$. Here our R2R method is trained on the images with various noise levels, and the obtained denoising model is relatively insensitive to the noise level. Thus, there is no need to recorrupt the test images, i.e., we use the trained model $F_{\theta^*}(\cdot)$ directly for prediction during testing.

In addition to two representative non-learning methods CBM3D and WNMM, two methods specifically designed for denoising real-world images are also included, namely multi-channel weighted nuclear norm minimization (MCWNNM) [34], and “noise clinic” (NC) method [19]. DnCNN, N2V and N2S are also retrained on SIDD-Medium for comparison, with (DnCNN) or without (N2V and N2S) calling the clean images in it. All the denoising methods are performed and evaluated on sRGB space.

Table 2. Quantitative comparison and Fig. 2 for visual comparison of some examples. It can be seen that the proposed R2R method outperformed all other non-learning methods and unsupervised methods. However, there is a noticeable performance gap between the R2R method and the supervised DnCNN, which may be caused by the inaccurate noise model and noise level function.

**CC and PolyU dataset without external noisy training samples.** For CC and PolyU, there is no training dataset available. Thus we train the denoiser on themselves directly without calling any external training samples. As noise characters are quite different for images captured under different conditions related to ISO level, shutter speed, illumination and other factors, we process these images individually. To obtain the results of DnCNN, we use the pre-trained blind DnCNN model for prediction, which are trained over the color version of BSD400 with AWGN where the noise level is uniformly sampled from [0, 55].

For sRGB images in CC and PolyU, the noise model (17) is not applicable as the gamma correction and tone mapping in the camera image processing procedure distorted the statistical characters of noise from raw images. Thus, we simply model the noise by AWGN with different noise levels in different color channels, the same as MCWNNM [34]. The noise level is estimated using the method [9]. Then we set $A = 20\sigma I$ and $B = \sigma I / 20$ in our recorruption scheme (10) for data generation with the estimated noise level $\sigma$ for each color channel. Here a relative large recorruption coefficient 20 is used because the noise level in images from CC and PolyU is low and heavier recorruption is better for avoiding overfitting. For each image, we train a DnCNN with 17 convolution layers for 8000 iterations using a learning rate of $10^{-3}$. It takes around half an hour to

process one image of size 512 × 512 × 3 for our method.

See Tab. 3 for the comparison of the R2R method to the pre-trained DnCNN and those methods that do not require any external training dataset, where N2V-single and N2S-single are the extensions of N2V and N2S to the case of single noisy image training. Our method still outperformed all other unsupervised deep learning methods by a large margin. There is a small advantages of our method over the top non-learning performer “MCWNNM” on the CC dataset, while a small disadvantages on the PolyU dataset. The pre-trained blind DnCNN performs poorly on CC and PolyU since it is trained on AWGN and generalizes poorly to the real noise. See Fig. 3 for visual comparison of some examples.

4.3. Ablation Study

This section is devoted to the ablation study for a better understanding of the proposed R2R method. We conduct the AWGN denoising experiments on BSD68 with noise level σ = 25, 50 in the following.

Performance gain from the prediction scheme (16). To show the benefit of the prediction scheme (16), we compare the result w/ it to the one w/o it. Tab. 4 shows that the performance gain brought by the scheme (16) is quite noticeable.

Performance impact of different value of α. Recall that we generate paired training data by (14) with \( D = \alpha I \) for AWGN removal. To show the impact of the recorruption factor \( \alpha \) on the performance, we compared the results yielded by using different values of \( \alpha \) in the range \([0, 1]\). It can be seen from Tab. 5 that the impact of different values of \( \alpha \) on the denoising performance is not significant.

Robustness to the estimation error of noise level. our method requires the prior knowledge on the noise levels of the training images to construct the pairs by (10). The sensitivity of our method to the estimation error of noise level is evaluated. The experiments are conducted by contaminating the estimation of noise s.t.d. with up to 10% error, i.e. the noise level is sampled uniformly from \([0.9\sigma, 1.1\sigma]\) to generate recorrupted images. It can be seen from Tab. 6 that the impact of such error on the performance is negligible, which indicates the robustness of the proposed R2R method to the estimation error of noise level.

5. Conclusion

In this paper, we proposed an unsupervised deep learning denoising method trained on unpaired noisy images and proved that our training scheme has the same loss function as that of the supervised training up to a constant. It is further demonstrated by the numerical results on AWGN denoising, where our method is comparable to the supervised baseline. For both AWGN denoising and real-world image denoising, our method achieved the competitive results compared to the SOTA unsupervised learning methods.

1. Proof of Theorem 1

\textit{Proof.} Denote $\hat{n} = n + Az$ and $\tilde{n} = n - Bz$. That is
\[
\begin{pmatrix}
\hat{n} \\
\tilde{n}
\end{pmatrix} = \begin{pmatrix}
I & A \\
I & -B
\end{pmatrix} \begin{pmatrix}
n \\
z
\end{pmatrix}.
\] (1)

Since $n \sim \mathcal{N}(0, \Sigma_x)$, $z \sim \mathcal{N}(0, I)$, and they are independent, we have
\[
\begin{pmatrix}
\hat{n} \\
\tilde{n}
\end{pmatrix} \sim \mathcal{N}(0, \Sigma'),
\] (2)

where
\[
\Sigma' = \begin{pmatrix}
I & A \\
I & -B
\end{pmatrix} \begin{pmatrix}
\Sigma_x & 0 \\
0 & I
\end{pmatrix} \begin{pmatrix}
I & A^\top \\
I & -B^\top
\end{pmatrix}
= \begin{pmatrix}
\Sigma_x + AA^\top & \Sigma_x - AB^\top \\
\Sigma_x - BA^\top & \Sigma_x + BB^\top
\end{pmatrix}
= \begin{pmatrix}
\Sigma_x + AA^\top & 0 \\
0 & \Sigma_x + BB^\top
\end{pmatrix}.
\] (3)

Thus, $\hat{n}$ and $\tilde{n}$ are also independent Gaussian random variables. It yields that
\[
\mathbb{E}_{x, \hat{n}, \tilde{n}} \left\{ \tilde{n}^\top \mathcal{F}_\theta(x + \hat{n}) \right\} = 0.
\]

Then our loss function can be rewritten as
\[
\begin{aligned}
\mathcal{L}(\theta; A, B) &= \mathbb{E}_{y, z} \| \mathcal{F}_\theta(y + Az) - (y - Bz) \|_2^2 = \mathbb{E}_{x, \hat{n}, \tilde{n}} \| \mathcal{F}_\theta(x + \hat{n}) - (x + \tilde{n}) \|_2^2 \\
 &= \mathbb{E}_{x, \hat{n}, \tilde{n}} \left\{ \| \mathcal{F}_\theta(x + \hat{n}) - x \|_2^2 - 2\tilde{n}^\top \mathcal{F}_\theta(x + \hat{n}) + 2\tilde{n}^\top x + \tilde{n}^\top \tilde{n} \right\} \\
 &= \mathbb{E}_{x, \hat{n}, \tilde{n}} \left\{ \| \mathcal{F}_\theta(x + \hat{n}) - x \|_2^2 + \mathbb{E}_x \text{trace}(\Sigma_x + BB^\top) \right\} \\
 &= \tilde{\mathcal{L}}(\theta; A) + \text{const}.
\end{aligned}
\] (4)

The proof is done. \qed

2. Running time

The inference time of processing the whole BSD68 dataset and SIDD Benchmark is around 115 seconds and 22 seconds respectively, on a NVIDIA TITAN RTX GPU with 24GB Memory. The reason why SIDD Benchmark is larger but takes less
time for inference is that the images in SIDD Benchmark are of the same size and can be processed in batch (a batch size of 32 is used by us), while the images in BSD68 vary in size and are processed one by one. Another cause is that, the AWGN denoiser is trained on the recorrupted images with specific noise level and thus the testing images in BSD68 are recorrupted for multiple times for prediction: \( \sum_{i=1}^{50} F_{\theta}^* (u + Az) \), while for SIDD Benchmark, the single forward prediction \( F_{\theta}^* (u) \) is enough since the trained real-world image denoiser is blind to noise level.

3. Visual Comparison of More Examples

In this section, we provide visual comparison of more examples on AWGN denoising and real-world image denoising. See Fig. 1 – 6.
