A LIKELIHOOD RATIO FRAMEWORK FOR HIGH-DIMENSIONAL SEMIPARAMETRIC REGRESSION

BY YANG NING*, TIANQI ZHAO† AND HAN LIU†

Cornell University* and Princeton University†

We propose a new inferential framework for high-dimensional semiparametric generalized linear models. This framework addresses a variety of challenging problems in high-dimensional data analysis, including incomplete data, selection bias and heterogeneity. Our work has three main contributions: (i) We develop a regularized statistical chromatography approach to infer the parameter of interest under the proposed semiparametric generalized linear model without the need of estimating the unknown base measure function. (ii) We propose a new likelihood ratio based framework to construct post-regularization confidence regions and tests for the low dimensional components of high-dimensional parameters. Unlike existing post-regularization inferential methods, our approach is based on a novel directional likelihood. (iii) We develop new concentration inequalities and normal approximation results for U-statistics with unbounded kernels, which are of independent interest. We further extend the theoretical results to the problems of missing data and multiple datasets inference. Extensive simulation studies and real data analysis are provided to illustrate the proposed approach.

1. Introduction. Modern data are characterized by their high dimensionality, complexity and heterogeneity. More specifically, the datasets usually contain (1) a large number of explanatory variables, (2) complex sampling and missing value schemes due to design or incapability of contacting study subjects and (3) heterogeneity due to the combination of different data sources. To handle these challenges, regularization based methods are proposed. For instance, the $L_1$-regularized maximum likelihood estimation for linear models is proposed by [36] and the nonconvex penalized maximum likelihood estimation is considered by [11]. During the past decades, these methods enjoy great success in handling high-dimensional data. However, the existing framework is not flexible enough to handle more challenging settings with incomplete data, complex sampling, and multiple heterogeneous datasets. To motivate our study, consider the following two examples.

EXAMPLE 1 (Missing data and selection bias). Given a univariate random variable $Y$ and a $d$ dimensional random vector $X$, assume that $Y$ given $X$ follows
from a generalized linear model with the canonical link,
\[(1.1) \quad p(y \mid x) = \exp\{x^T \beta \cdot y - b(x^T \beta, f) + \log f(y)\},\]

where \(\beta\) is a \(d\)-dimensional unknown parameter, \(f(\cdot)\) is a known base measure function and \(b(\cdot, \cdot)\) is a normalizing function. Let \((Y_1, X_1), \ldots, (Y_n, X_n)\) denote \(n\) independent copies of \((Y, X)\). In high-dimensional data analysis, the samples \((Y_1, X_1), \ldots, (Y_n, X_n)\) may contain missing values or they are observed after some unknown selection process. To account for the effect of missingness or selection bias, we introduce an indicator variable \(\delta_i\), whose value is 1 if \((Y_i, X_i)\) is completely observed or selected, and 0 otherwise. Due to the selection effect, the standard penalized maximum likelihood estimator under model \((1.1)\) with only selected data (i.e., \(\delta_i = 1\)) is often inconsistent for \(\beta\). To account for the missing data and selection bias, we need to develop a new framework to infer the high-dimensional parameter \(\beta\).

**Example 2** (Multiple datasets inference with heterogeneity). Modern datasets are often collected by aggregating multiple data sources. Analysis of such types of data has been studied in the fields of multitask learning in machine learning [1, 22] and seemingly unrelated regression in econometrics [33]. In the multitask learning setting, each dataset corresponds to a learning task. More specifically, assume that the data in the \(t\)th task, \(t = 1, \ldots, T\) are i.i.d. copies of \((Y^{(t)}, X^{(t)})\), which follows from \((1.1)\), that is,
\[(1.2) \quad p(y^{(t)} \mid x^{(t)}) = \exp\{x^{(t)T} \beta^{(t)} \cdot y^{(t)} - b(x^{(t)T} \beta^{(t)}, f_t) + \log f_t(y^{(t)})\},\]

where \(\beta^{(t)}\) is a task-specific regression parameter. Most of the existing literature only focuses on the analysis of homogeneous datasets that means \(f_t(\cdot) = f(\cdot)\) for any \(t = 1, \ldots, T\). However, the aggregated data are often highly heterogeneous. For instance, the learning tasks obtained from different areas may contain classification for binary responses as well as regression for continuous and count responses, which implies different forms of \(f_t(\cdot)\) in \((1.2)\). Thus, to take into account data heterogeneity, we need a new inferential procedure for \(\beta^{(t)}\) that does not depend on the knowledge of \(f_t(\cdot)\).

To handle the above challenges, we propose a new semiparametric model, which takes the form \((1.1)\) but with both \(\beta\) and \(f(\cdot)\) as unknown parameters. It naturally handles data with missing values, complex sampling and heterogeneity. This paper contains three major contributions.

Our first contribution is to provide a new regularized statistical chromatography procedure to directly estimate the finite dimensional regression parameter \(\beta\) and leave the nonparametric component \(f(\cdot)\) as a nuisance. In particular, we model the data at a more refined granularity of rank and order statistics, so that sophisticated conditioning arguments and the structure of exponential family distributions can
be exploited to separate the parameter of interest and nuisance component (thus the whole procedure is named “statistical chromatography”). Once the parameter of interest and nuisance parameter are separated, we eliminate the nuisance component to construct a pseudo-likelihood of rank statistics and exploit lower order approximation to speed up computation.

Our second contribution is to develop a new likelihood ratio inferential framework for low-dimensional parameters under the high-dimensional model. In particular, we propose a directional likelihood ratio statistic for hypothesis testing and a maximum directional likelihood estimator for confidence regions in the high-dimensional setting. Compared to the existing post-regularization inferential methods, our procedure has two important features: (1) We allow general regularized estimators including nonconvex regularized estimators and pseudo-likelihood; and (2) We do not need any signal strength assumption for model selection consistency. Our third contribution is to develop new technical tools for studying high-dimensional inference related to U-statistics. First, we prove a concentration inequality in Lemma A.3 for U-statistics with unbounded kernels with subexponential decay. A more general maximal inequality is shown in Lemma F.2 of Supplementary Material [29], which plays the key role to derive improved rates of convergence for multiple datasets inference problems. Second, to apply the central limit theorem for U-statistics, we provide the theoretical justification of the Hájek projection in increasing dimensions for normal approximation. More details are provided in Lemma A.5. These U-statistic results are of independent interest.

Comparison with related works: The proposed model is closely related to the proportional likelihood ratio model [7, 23]. However, unlike their model we do not require the density assumption for the nonparametric function. The proposed estimation procedure is related to the permutation based test [16] and the second-order approximation reduces to the pairwise likelihood considered by [7, 18]. To the best of our knowledge, the proposed estimation method dates back to the original work by [18], in which a pairwise likelihood method is used to eliminate the nonparametric function. We follow their idea and generalize it to the missing data and multitask learning problems. Our investigation mainly focuses on the theoretical properties in high-dimensional regimes, which have not been studied before.

In the literature, a marginal rank likelihood method is proposed to eliminate the nuisance functions in the linear transformation model [30] and the copula model [14]. However, unlike the marginal rank likelihood, our likelihood function can be viewed as a conditional rank likelihood constructed by the conditional rank probability given the order statistics. To handle high-dimensional data with missing values, [34] proposed an expectation-maximization algorithm. When the explanatory variables are missing completely at random (MCAR), Loh and Wainwright [20] developed the theory of a nonconvex optimization approach. Compared with these works, we consider a much broader class of missing data mechanisms.

In the linear models, the estimation, prediction error bounds and variable selection consistency for the $L_1$-regularized estimator have been well studied by
[5, 6, 24, 27, 42]. More recently, the estimation bounds and oracle properties for the nonconvex regularized estimator are established by [12, 21, 38], among others. In addition to these estimation results, significant progress has been made toward understanding the high-dimensional inference (e.g., constructing confidence intervals or testing hypotheses) under the generalized linear models. Examples include [2–4, 15, 37, 41]. All these procedures lead to asymptotically normally distributed estimators that can be used to construct Wald-type statistics. Other related inferential procedures include the data-splitting method [26, 39], stability selection [25, 32], $L_2$ confidence set [28] and conditional inference [19, 35]. Under a stronger oracle property, the asymptotic normality of nonconvex estimators is established by [11].

This paper proposes a new directional likelihood based method for constructing confidence regions and testing hypotheses in high dimensions. Compared to the existing work on high-dimensional inference under the generalized linear model, our method and theory are different in the following three aspects. First, our proposed semiparametric model is much more sophisticated than the generalized linear model. In particular, the U-statistic structure due to the statistical chromatography leads to additional technical challenge (see the third contribution above) and requires more refined analysis to control the variability of the estimated nuisance parameters in the proposed directional likelihood function. Second, from the hypothesis testing perspective, our main inferential tool is a new directional likelihood ratio test, whereas the existing methods mainly focus on the Wald or score-type tests. Third, we can conduct the inference based on local solutions of a nonconvex regularized problem, while the method in [37] based on inverting the Karush–Kuhn–Tucker condition may not be directly applicable.

The rest of this paper is organized as follows. In Section 2, we formally define the proposed semiparametric model. In Section 3, we introduce the main ideas of regularized statistical chromatography, along with the directional likelihood based inference for hypothesis tests and confidence regions. In Section 4, we analyze the theoretical properties of the obtained confidence regions and establish the asymptotic distributions of the directional likelihood ratio test statistics. Section 5 contains both simulation and real data analysis results. The last section includes remarks and discussions. The proofs of main results are shown in the Appendix.

Notation: For positive sequences $a_n$ and $b_n$, we write $a_n \preceq b_n$, if $a_n/b_n = O(1)$. We denote $a_n \asymp b_n$ if $a_n \lesssim b_n$ and $b_n \lesssim a_n$. Denote $X_n \rightsquigarrow X$ for some random variable $X$ if $X_n$ converges weakly to $X$. For $v = (v_1, \ldots, v_d)^T \in \mathbb{R}^d$, and $1 \leq q \leq \infty$, we define $\|v\|_q = (\sum_{i=1}^d |v_i|^q)^{1/q}$, $\|v\|_0 = |\text{supp}(v)|$, where $\text{supp}(v) = \{j : v_j \neq 0\}$ and $|A|$ is the cardinality of a set $A$. Denote $\|v\|_\infty = \max_{1 \leq i \leq d} |v_i|$ and $v^{\otimes 2} = vv^T$. For a matrix $M$, let $\|M\|_2$, $\|M\|_\infty$, $\|M\|_1$ and $\|M\|_{L_1}$ be the spectral, elementwise supreme, elementwise $L_1$ and matrix $L_1$ norms of $M$. For two matrices $M_1$ and $M_2$, we write $M_1 \preceq M_2$ if $M_2 - M_1$ is positive semidefinite. For $S \subseteq \{1, \ldots, d\}$, let $v_S = \{v_j : j \in S\}$ and $S^c$ be the complement of $S$. The gradient and subgradient of a function $f(x)$ are denoted by $\nabla f(x)$ and $\partial f(x)$, respectively.
For a univariate function $f(x)$, its derivative can also be represented by $f'(x)$. Let $\nabla_S f(x)$ denote the gradient of $f(x)$ with respect to $x_S$. Let $I_d$ be the $d$ by $d$ identity matrix. Let $\lfloor k \rfloor$ denote the largest integer less than $k$. Throughout the paper, we use bold letters to denote vectors and matrices and unbold letters to denote scalars. We use the following definition of subexponential random variables.

**Definition 1.1.** A random variable $Y$ is subexponential if there exist constants $C, C' > 0$, such that $P(|Y| \geq \delta) \leq C' \exp(-C\delta)$, for any $\delta > 0$.

2. The semiparametric generalized linear model. We first define a semiparametric natural exponential family model, which further leads to the definition of the semiparametric generalized linear model.

**Definition 2.1 (Semiparametric natural exponential family).** A random variable $Y \in \mathcal{Y} \subseteq \mathbb{R}$ satisfies the semiparametric natural exponential family (spEF) with parameters $(\theta, f)$, if its density satisfies

$$
(2.1) \quad p(y; \theta, f) = \exp\{\theta \cdot y - b(\theta, f) + \log f(y)\},
$$

where $f(\cdot)$ is an unknown base measure, $\theta$ is an unknown canonical parameter, and $b(\theta, f) = \log \int_{\mathcal{Y}} f(y) \cdot dy < \infty$ is the log-partition function.

The spEF extends the classical natural exponential family by treating the base measure $f(y)$ as an infinite dimensional parameter. By choosing a suitable base measure, the spEF recovers the whole class of natural exponential family distributions. However, the spEF suffers from the identifiability issue. For instance, spEF$(\theta, f)$ is identical to spEF$(\theta, c \cdot f)$, where $c$ is any positive constant. To address this problem, we need to impose some identifiability conditions, such as $f(y_0) = 1$, for some $y_0 \in \mathcal{Y}$, or $\int_{\mathcal{Y}} f(y) \cdot dy = 1$ if $f(y)$ is integrable. Later, we can see that these identifiability conditions will not affect our inference procedures. We now define the semiparametric generalized linear model.

**Definition 2.2 (Semiparametric generalized linear model).** Given a vector of $d$-dimensional covariates $X = (X_1, \ldots, X_d)^T$ and response $Y \in \mathbb{R}$, assume $Y$ given $X$ follows the semiparametric natural exponential family

$$
(2.2) \quad p(y | x) = \exp\{\theta(x) \cdot y - b(\theta(x), f) + \log f(y)\} \quad \text{and} \quad \theta(x) = \beta^T x,
$$

where $b(\cdot, \cdot)$ is the log-partition function and $\beta$ is a $d$-dimensional parameter. We say that $Y$ given $X$ follows the semiparametric generalized linear model (GLM) with parameters $(\beta, f)$.

Note that we directly set $\theta(x) = \beta^T x$ in (2.2), because we implicitly adopt the canonical link, that is, we choose a link function $g$ such that $g^{-1}(\cdot) = b'(\cdot, f)$. Compared with the classical generalized linear models (GLMs), the proposed
model contains unknown parameters $\beta$ and $f(\cdot)$, where $\beta$ characterizes the covariate effect, and $f(\cdot)$ determines the distribution in the natural exponential family. For instance, the linear regression with standard Gaussian noise has $f(y) = \exp(-y^2/2)$; the logistic regression has $f(y) = 1$; and the Poisson regression has $f(y) = 1/y!$. Thus, these GLMs are parametric submodels of the semiparametric generalized linear model.

**Remark 1.** Some exponential family distributions, such as the normal distribution, involve dispersion parameters. In this case, the semiparametric natural exponential family can be written as

$$p(y; \theta, \tau, f) = \exp\left\{\theta \cdot y - b(\theta, f)\right\}/a(\tau) + \log f(y; \tau),$$

where $f(\cdot; \cdot)$ is an unknown positive function, $\theta$ is the natural parameter, $a(\tau)$ is a known function of the dispersion parameter $\tau$ and $b(\theta, f)$ is the log-partition function. Then, with $\theta(x) = \beta^T x$, the semiparametric generalized linear model reduces to

$$p(y \mid x; \beta, \tau, f) = \exp\{\bar{\beta}^T x \cdot y - \bar{b}(\bar{\beta}^T x, \tau, f)\} + \log f(y; \tau),$$

where $\bar{\beta} = \beta/a(\tau)$ and $\bar{b}(\bar{\beta}^T x, \tau, f) = b(a(\tau)\beta^T x, f)/a(\tau)$. Hence, with the new reparametrization $\bar{\beta}$, the proposed model is identical to (2.2), except that we allow $\bar{b}(\cdot)$ and $f(\cdot; \cdot)$ to depend on the dispersion parameter $\tau$. Later, we will see that this dependence does not lead to any extra level of difficulty in terms of inference on $\bar{\beta}$.

The semiparametric generalized linear model has broad applicability to address the challenging problems involving complex and heterogeneous data. In the following, we illustrate how the semiparametric model can be used to handle the missing data and selection bias problems in Example 1 and heterogeneous multi-task learning problem in Example 2.

**Revisit of Example 1: Missing data and selection bias.** Recall that $Y_i$ given $X_i$ follows the GLM in (1.1) and we are interested in making inference on $\beta$. To account for the missing data and selection effect, we assume that the selection indicator $\delta_i$ given $Y_i$ and $X_i$ satisfies the following decomposable selection model.

**Definition 2.3** (Decomposable selection model). The missing data or selection model is decomposable, if there exist two nonnegative functions $g_1(\cdot)$ and $g_2(\cdot)$ such that $\mathbb{P}(\delta_i = 1 \mid Y_i, X_i) = g_1(Y_i) \cdot g_2(X_i)$, where $\int g_1(y) \cdot dy = 1$ and $\int g_2(x) \cdot dx = 1$.

Under the assumption of MCAR, the missing data model satisfies $\mathbb{P}(\delta_i = 1 \mid Y_i, X_i) = \mathbb{P}(\delta_i = 1)$, which implies that MCAR is decomposable. Indeed, the decomposable model is much more general. Consider the following partition of
covariates $X_i = (X_{io}, X_{im})$, and assume that $(Y_i, X_{im})$ are subject to missingness. It is seen that the missing at random (MAR), defined by $\mathbb{P}(\delta_i = 1|Y_i, X_i) = \mathbb{P}(\delta_i = 1|X_{io})$, is also decomposable. So is the outcome dependent sampling model [17]. In addition, the decomposable model can be missing not at random (MNAR). For instance, if $Y_i$ is subject to missingness and the missing mechanism only depends on the potentially unobserved value of $Y_i$, then the missing data pattern is not at random but is still decomposable. Thus, the decomposable selection model is a very flexible nonparametric model for missing data and selection bias. In general, the functions $g_1(\cdot)$ and $g_2(\cdot)$ may not be identifiable. Later, we will see that this nonidentifiability issue can be handled by using the proposed method.

To specify the likelihood based on the selected data, we derive the probability density function of $Y_i$ given $X_i$ and $\delta_i = 1$. Using the Bayes formula,

$$p(y_i \mid x_i, \delta_i = 1) = \mathbb{P}(\delta_i = 1 \mid y_i, x_i) \cdot p(y_i \mid x_i)/T_i(x_i),$$

where $T_i(x_i) = \int \mathbb{P}(\delta_i = 1 \mid y_i, x_i) p(y_i \mid x_i) dy$ and $(y_i, x_i)$ is the observed value of $(Y_i, X_i)$. Under the generalized linear model in (1.1) and the decomposable selection model, we obtain

$$p(y_i \mid x_i, \delta_i = 1) = \exp\{x_i^T \beta \cdot y_i - b(x_i^T \beta, f^m) + \log f^m(y_i)\},$$

where $f^m(y) = g_1(y) f(y)$. Hence, if $Y_i$ given $X_i$ follows the GLM (1.1) or more generally the semiparametric version (2.2) and the selection model is decomposable, then $Y_i$ given $X_i$ and $\delta_i = 1$ satisfies (2.2) with the same unknown parameter $\beta$ and the unknown based measure $f^m(y) = g_1(y) f(y)$. We call this the invariance property of semiparametric GLMs under the decomposable selection model. Hence, the inference on $\beta$ with missing data and selection bias is equivalent to the inference problem under the semiparametric GLM (2.2).

**Revisit of Example 2: Multiple datasets inference with heterogeneity.** In Example 2 of Section 1, to take into account of data heterogeneity, we can assume that the based measure function $f_i(\cdot)$ is a task-specific unknown function. Thus, the multiple datasets inference with heterogeneity can be handled by the semiparametric GLM framework, and an inferential method that is invariant to $f(\cdot)$ under the model (2.2) is needed.

### 3. Semiparametric inference

In this section, we consider how to construct confidence intervals and perform hypothesis tests for a single component of $\beta$ under the semiparametric GLM. The extension to the confidence regions and tests for multidimensional components of $\beta$ is standard and is deferred to the Supplementary Material [29].

#### 3.1. Regularized statistical chromatography

Due to the presence of the unknown function $f(\cdot)$, the likelihood of the semiparametric GLM is complicated, making likelihood based inference of $\beta$ intractable. To handle this problem, we
propose a new procedure called statistical chromatography to extract information on $\beta$.

For $i = 1, \ldots, n$, suppose that the data $(Y_i, X_i)$ are i.i.d. By the discriminative modeling approach, the probability distribution of the data is $p(y | x; \beta, f) = p(y | x; \beta, f) \cdot p(x)$, where $y = (y_1, \ldots, y_n)$ and $x = (x_1, \ldots, x_n)$ are the observed values of $Y = (Y_1, \ldots, Y_n)$ and $X = (X_1, \ldots, X_n)$. Since the marginal distribution of $X$ does not involve $\beta$ or $f$, we only focus on the first conditional distribution $p(y | x; \beta, f)$. However, its dependence on $\beta$ and $f$ is still intertwined and the inference on $\beta$ is hindered by the nuisance parameter $f$. To tackle this problem, we need to further separate the parameters $\beta$ and $f$ in the conditional likelihood. To this end, we decompose $Y = (Y_1, \ldots, Y_n)$ into $R = (R_1, \ldots, R_n)$ and $Y(\cdot) = (Y(1), \ldots, Y(n))$, which denote the rank and order statistics of $Y$, respectively. Let $r$ and $y(\cdot)$ denote the observed values of $R$ and $Y(\cdot)$, respectively. Thus, we have

\begin{equation}
    p(y | x; \beta, f) = \mathbb{P}(R = r | x, y(\cdot); \beta) \cdot p(y(\cdot) | x; \beta, f),
\end{equation}

where by the definition of conditional probabilities we can show that

\begin{equation}
    \mathbb{P}(R = r | x, y(\cdot); \beta) = \frac{\prod_{i=1}^{n} p(y_i | x_i; \beta, f)}{\sum_{\pi \in \Xi} \prod_{i=1}^{n} p(y_{\pi(i)} | x_i; \beta, f)} = \frac{\exp(\sum_{i=1}^{n} \beta^T x_i \cdot y_i)}{\sum_{\pi \in \Xi} \exp(\sum_{i=1}^{n} \beta^T x_i \cdot y_{\pi(i)})},
\end{equation}

where $\Xi$ is the set of all one-to-one maps from $\{1, \ldots, n\}$ to $\{1, \ldots, n\}$. The intuition behind the data decomposition is that the rank statistic given the order statistic has no information on $f$. Mathematically, the product $\prod_{i=1}^{n} f(y_i)$ appearing in both numerator and denominator of (3.2) only depends on $Y(\cdot)$ and is eliminated. Since we separate parameters $\beta$ and $f$ at a more refined granularity of rank and order statistics, we call this procedure as statistical chromatography.

Given the chromatography decomposition in (3.1), one may opt to only keep the conditional probability (3.2) for estimation and inference of $\beta$. However, the probability in (3.2) is computationally intensive due to the combinatorial nature of permutations. To this end, we consider a surrogate of $\mathbb{P}(R = r | x, y(\cdot); \beta)$ using the $k$th order information. For notational simplicity, we only present $k = 2$, and leave the discussion for $k > 2$ to the Supplementary Material [29]. For any $i$ and $j$, let $R_{ij}^L$ denote the local rank statistic of $Y_j$ and $Y_j$ among the pair $(Y_i, Y_j)$ [i.e., $R_{ij}^L = (1, 2)$ or $(2, 1)$]. Instead of considering the full conditional probability in (3.2), we study the product of all possible combinations of the local rank conditional probability,

\begin{equation}
    \prod_{i<j} \mathbb{P}(R_{ij}^L = r_{ij}^L | x_i, x_j, y(\cdot); \beta)
\end{equation}

\begin{equation}
    = \prod_{i<j} \frac{\exp(\beta^T x_i y_i + \beta^T x_j y_j)}{\exp(\beta^T x_i y_i + \beta^T x_j y_j) + \exp(\beta^T x_i y_j + \beta^T x_j y_i)},
\end{equation}
where $Y_{(i,j)}^L = (\min(Y_i, Y_j), \max(Y_i, Y_j))$, and $y^L_{(i,j)}$ and $r_{ij}^L$ are the observed values of $Y_{(i,j)}^L$ and $R_{ij}^L$, respectively. Applying the logarithmic transformation to (3.3), we obtain the function

$$
\ell(\beta) = -\left(\frac{n}{2}\right)^{-1} \sum_{1 \leq i < j \leq n} \log(1 + R_{ij}(\beta)),
$$

where $R_{ij}(\beta) = \exp\{- (y_i - y_j) \cdot \beta^T (x_i - x_j)\}$. It is also known as the pairwise log-likelihood, which has been considered by [7, 8, 18]. In high dimensions, we may add a regularization term to $\ell(\beta)$, which leads to the regularized chromatography approach.

3.2. Confidence interval and hypothesis test: A likelihood ratio approach. Given the composite log-likelihood (3.4), we consider the problem of testing a pre-specified component of $\beta$. Without loss of generality, assume that $\beta$ can be partitioned as $\beta = (\alpha, \gamma^T)^T$, where $\alpha \in \mathbb{R}$ and $\gamma \in \mathbb{R}^{d-1}$. Now, we consider the null hypothesis $H_0 : \alpha = \alpha_0$, and treat $\gamma$ as a $(d-1)$-dimensional nuisance parameter. Let $\beta^*$ be the true value of $\beta$. It is well known that the classical likelihood ratio test is not directly applicable to testing the null hypothesis $H_0$, when the nuisance parameter $\gamma$ is high dimensional. In what follows, we propose a new directional likelihood function and the corresponding likelihood ratio test for $H_0$, which provides valid inferential results in high-dimensional settings.

Specifically, we define the directional likelihood function for $\alpha$ as

$$
\hat{\ell}(\alpha) = \ell(\alpha, \hat{\gamma} + (\hat{\alpha} - \alpha)\hat{w}),
$$

where $\hat{\beta} := (\hat{\alpha}, \hat{\gamma})$ is an initial estimator for $\beta^*$, and $\hat{w}$ is an estimator for

$$
w^* := H_{\alpha \gamma}(H_{\gamma \gamma})^{-1} \in \mathbb{R}^{d-1} \quad \text{where} \quad H = -\mathbb{E}\{\nabla^2 \ell(\beta^*)\}.
$$

Here, the estimators $\hat{\beta}$ and $\hat{w}$ will be introduced later and $H_{\alpha \gamma}$ and $H_{\gamma \gamma}$ are the corresponding partitions of $H$. Later, we can show that the directional likelihood function $\hat{\ell}(\alpha)$ can be treated as a standard likelihood function for a single unknown parameter $\alpha$. For instance, we define the maximum directional likelihood estimator as

$$
\hat{\alpha}^P = \arg\max_{\alpha \in \mathbb{R}} \hat{\ell}(\alpha).
$$

To test the null hypothesis $H_0 : \alpha^* = \alpha_0$, we define the maximum directional likelihood ratio test (DLRT) statistic as

$$
\Lambda_n = 2n \{ \hat{\ell}(\hat{\alpha}^P) - \hat{\ell}(\alpha_0) \}.
$$

In the following, we explain the intuition behind the directional likelihood (3.5) based on the geometry of submodels in the semiparametric literature and the orthogonality property for nuisance parameters. We note that a similar orthogonality
property has been used by [3, 4] for the post-selection inference. We leave the
detailed comparison and discussion to Remark 2.

Given the likelihood function \( \ell(\beta) \), we consider a parametrization for a surface
\( S \subset \mathbb{R}^{d+1} \), in which the coordinates of points can be expressed as \((\beta, \ell(\beta)) \in \mathbb{R}^{d+1}\). Consider two smooth functions \( \alpha(\cdot) \in \mathbb{R} \) and \( \gamma(\cdot) \in \mathbb{R}^{d-1} \), satisfying
\( \alpha(0) = \alpha^*, \alpha'(0) \neq 0 \) and \( \gamma(0) = \gamma^* \). Define a smooth curve \( \delta : I \to \mathbb{R}^{d+1} \), which maps \( t \in I \) to \((\alpha(t), \gamma(t), \ell_c(t)) \), where \( I \) is an interval in \( \mathbb{R} \) containing a small neighborhood of \( 0 \) and \( \ell_c(t) = \ell(\alpha(t), \gamma(t)) \). Note that the curve \( \delta \) is within the surface \( S \) and passes through the true values \((\alpha^*, \gamma^*, \ell(\beta^*)) \) when \( t = 0 \). Since the curve \( \delta \) is determined by the form of \((\alpha(t), \gamma(t)) \), we need to decide how to choose \((\alpha(t), \gamma(t)) \) such that the likelihood \( \ell_c(t) \) along the curve has desired properties. Taking the derivative with respect to \( t \), the score function of \( \ell_c(t) \) at \( t = 0 \) is given by

\[
S_c(\alpha^*, \gamma^*) := \frac{d \ell_c(t)}{dt} \bigg|_{t=0} = \alpha'(0) \cdot \nabla_\alpha \ell(\alpha^*, \gamma^*) + [\gamma'(0)]^T \cdot \nabla_\gamma \ell(\alpha^*, \gamma^*) .
\]

To construct a valid test statistic, the key insight is to ensure that \( S_c(\alpha, \gamma) \) is robust
to the perturbation of the high-dimensional nuisance parameter \( \gamma \). Mathematically, we require the following orthogonality property, that is, \( \mathbb{E}[\nabla_\gamma S_c(\alpha^*, \gamma^*)] = 0 \); see Remark 2 for further discussion. This implies \( \alpha'(0) \mathbb{H}_{\alpha \gamma} + [\gamma'(0)]^T \mathbb{H}_{\gamma \gamma} = 0 \), which is equivalent to \( \gamma'(0)/\alpha'(0) = -\mathbf{w}^* \) by (3.6). Thus, for \( t \) in a small neighb-

orhood of \( 0 \), the Taylor theorem implies

\[
\alpha(t) = \alpha^* + \alpha'(0)t + o(t) \quad \text{and} \quad \gamma_j(t) = \gamma_j^* - \alpha'(0)w_j^*t + o(t),
\]

where \( 1 \leq j \leq d - 1 \). Ignoring the higher order terms, this gives \( \ell_c(t) = \ell(\alpha^* + \alpha'(0)t, \gamma^* - \alpha'(0)w^*t) \). Finally, a reparametrization of \( \ell_c(t) \) with \( \alpha := \alpha^* + \alpha'(0)t \) yields a function \( \tilde{\ell}_c(\alpha) \) of \( \alpha \), defined as

\[
\tilde{\ell}_c(\alpha) := \ell_c\left(\frac{\alpha - \alpha^*}{\alpha'(0)}\right) = \ell(\alpha, \gamma^* + (\alpha^* - \alpha)\mathbf{w}^*).
\]

Replacing \( \alpha^*, \gamma^* \) and \( \mathbf{w}^* \) by the corresponding estimators \( \hat{\alpha}, \hat{\gamma} \) and \( \hat{\mathbf{w}} \), the function
\( \tilde{\ell}_c(\alpha) \) becomes the directional likelihood in (3.5). This gives the geometric intu-
tion on how the directional likelihood is derived. When \( \ell(\beta) \) is the log-likelihood function, the curve \((\alpha(t), \gamma(t)) \) corresponds to the least favorable curve up to a reparametrization [31].

Next, we consider how to obtain estimators \( \hat{\alpha}, \hat{\gamma} \) and \( \hat{\mathbf{w}} \) in the directional like-
lihood (3.5). To estimate \( \beta^* \), our proposed framework allows a wide class of estim-
ators \( \hat{\beta} = (\hat{\alpha}, \hat{\gamma}) \) including the regularized estimators with nonconvex (or folded concave) penalty functions; see Remark 3. To estimate the \((d-1)\)-dimensional
vector $w^*$, we use the following Lasso-type estimator:

$$\hat{w} = \arg\max_w \left\{ \frac{1}{2} w^T \nabla^2_{\gamma \gamma} \ell(\hat{\beta}) w - w^T \nabla^2_{\gamma \alpha} \ell(\hat{\beta}) - \lambda_1 \|w\| \right\}. \tag{3.9}$$

where $\lambda_1 \geq 0$ is a tuning parameter.

To analyze the semiparametric GLM, one technical challenge is that $\nabla \ell(\beta)$ is a high-dimensional U-statistic with a possibly unbounded kernel function, that is,

$$\nabla \ell(\beta) = \frac{2}{n(n-1)} \sum_{1 \leq i < j \leq n} \frac{R_{ij}(\beta) \cdot (y_i - y_j) \cdot (x_i - x_j)}{1 + R_{ij}(\beta)}.$$

To decouple the correlation between summands in $\nabla \ell(\beta)$, we resort to the Hájek projection [13] and define

$$\hat{U}_n = \frac{2}{n} \sum_{i=1}^{n} g(y_i, x_i, \beta^*) \quad \text{where} \quad g(y_i, x_i, \beta) = \frac{n}{2} \cdot \mathbb{E}[\nabla \ell(\beta) | y_i, x_i]. \tag{3.10}$$

By definition, $2n^{-1}g(y_i, x_i, \beta^*)$ is the projection of $\nabla \ell(\beta^*)$ onto the $\sigma$-field generated by $(y_i, x_i)$, and we sum over all samples to construct $\hat{U}_n$. We therefore approximate the U-statistic $\nabla \ell(\beta^*)$ by the sum of independent random variables $\hat{U}_n$. Let $\Sigma = \mathbb{E}[(g^*)_2]$ denote the variance of $g_i^*$, where $g_i^* = g(y_i, x_i, \beta^*)$. In Theorem 4.1, we prove

$$n^{1/2} \cdot (\hat{\alpha}^P - \alpha^*) \rightsquigarrow N(0, 4 \cdot \sigma^2 \cdot H_{\alpha|\gamma}^{-2}),$$

where $\sigma^2 = \Sigma_{\alpha\alpha} - 2w^T \Sigma_{\gamma\alpha} + w^T \Sigma_{\gamma\gamma} w^*$, $H_{\alpha|\gamma} = H_{\alpha\alpha} - H_{\alpha\gamma} H_{\gamma\gamma}^{-1} H_{\gamma\alpha}$ and $\Sigma_{\alpha\alpha}$, $\Sigma_{\gamma\alpha}$ and $\Sigma_{\gamma\gamma}$ are corresponding partitions of $\Sigma$. To construct confidence intervals and Wald-type hypothesis test, one needs to estimate the asymptotic variance, which depends on the unknown covariance and Hessian matrices $\Sigma$ and $H$. By exploiting the U-statistic structure of $\nabla \ell(\beta)$, we can estimate $\Sigma$ by

$$\hat{\Sigma} = \frac{1}{n} \sum_{i=1}^{n} \left\{ \frac{1}{n-1} \sum_{j=1, j \neq i}^{n} \frac{R_{ij}(\hat{\beta}) \cdot (y_i - y_j) \cdot (x_i - x_j)}{1 + R_{ij}(\hat{\beta})} \right\}^{\otimes 2}. \tag{3.11}$$

Thus, we define $\hat{\sigma}^2 = \hat{\Sigma}_{\alpha\alpha} - 2\hat{w}^T \hat{\Sigma}_{\gamma\alpha} + \hat{w}^T \hat{\Sigma}_{\gamma\gamma} \hat{w}$. Moreover, we can estimate $H_{\alpha|\gamma}$ by $\hat{H}_{\alpha|\gamma} = -\nabla^2_{\alpha\alpha} \ell(\hat{\beta}) + \hat{w}^T \nabla^2_{\gamma\alpha} \ell(\hat{\beta})$. Therefore, a two-sided confidence interval for $\alpha^*$ with $(1 - \xi)$ coverage probability is given by $[\hat{\alpha}^P - \xi n^{-1/2}, \hat{\alpha}^P + \xi n^{-1/2}]$, where $\xi = 2\hat{\sigma} \hat{H}_{\alpha|\gamma}^{-1} \Phi^{-1}(1 - \xi/2)$.

In addition, to test the null hypothesis $H_0 : \alpha^* = \alpha_0$, Theorem 4.2 shows that the maximum directional likelihood ratio test statistic $\Lambda_n$ in (3.8) satisfies $(4\sigma^2)^{-1}H_{\alpha|\gamma}\Lambda_n \rightsquigarrow \chi^2_1$. Hence our test with the significance level $\xi$ is

$$\psi_{DLRT}(\xi) = \mathbb{I}\{(4 \cdot \hat{\sigma}^2)^{-1} \cdot \hat{H}_{\alpha|\gamma} \cdot \Lambda_n \geq \chi^2_{1, \xi} \}, \tag{3.12}$$

where $\chi^2_{1, \xi}$ is the $(1 - \xi)$th quantile of a $\chi^2_1$ random variable. The null hypothesis is rejected if and only if $\psi_{DLRT}(\xi) = 1$, and the associated p-value is given by
\[ P_{\text{DLRT}} = 1 - \chi_1^2((4\bar{\sigma}^2)^{-1}\tilde{H}_{\alpha|\gamma}\Lambda_{n}), \]
where \( \chi_1^2(\cdot) \) is the c.d.f. of a chi-squared distribution with degree of freedom 1. In Corollary 4.2, we prove that the proposed test can control the type I error asymptotically, that is, \( \lim_{n \to \infty} P(\psi_{\text{DLRT}}(\xi) = 1 \mid H_0) = \xi \) and the p-value is asymptotically uniformly distributed, that is, \( P_{\text{DLRT}} \to \text{Uniform}[0, 1] \), under \( H_0 \).

**Remark 2 (Orthogonality condition).** Recall that the orthogonality condition plays an important role in deciding the direction of the curve \( \delta \) at \( t = 0 \) in our geometric interpretation. Under the GLM and the median regression, \([4]\) and \([3]\) developed an alternative method based on a similar orthogonality property, called immunization, to perform post-selection inference. For instance, in the context of the logistic regression model, the key idea of \([4]\) is to construct an instrument \( z_i = z(x_i) \in \mathbb{R} \) such that the orthogonality condition \( \nabla_\gamma \mathbb{E}[(y_i - G(\beta^T x_i))z_i] = 0 \) holds, where \( G(\cdot) = \exp(\cdot)/(1 + \exp(\cdot)) \). Their test statistic for \( H_0 : \alpha^* = \alpha_0 \) is given by \( T_n = n^{-1}\sum_{i=1}^{n}[y_i - G(\tilde{\beta}_0^T x_i)]\tilde{z}_i \), where \( \tilde{\beta}_0 = (\alpha_0, \gamma) \) for some regularized estimator \( \tilde{\gamma} \) and \( \tilde{z}_i \) is an estimate of \( z_i \). They proved that under regularity conditions \( n^{1/2}T_n \) is asymptotically normal with mean 0 and the variance can be consistently estimated. Our likelihood ratio method is different in the following two aspects. First, while our procedure also relies on a similar orthogonality condition, we do not explicitly construct the instrumental variable \( z_i \) in our testing procedure. Second, our test statistic is different. Namely, their test statistic \( T_n \) is based on the sample version of the moment condition \( \mathbb{E}[(y_i - G(\beta^T x_i))z_i] = 0 \), whereas our test statistic \( \Lambda_n \) in (3.8) is based on the ratio of the directional likelihood.

**4. Main results.** We first prove the asymptotic normality of the maximum directional likelihood estimator \( \hat{\alpha}^P \) in (3.7). We then derive the limiting distribution of \( \Lambda_n \) as well as the validity of the maximum directional likelihood ratio test in (3.12) under the null hypothesis \( H_0 : \alpha^* = \alpha_0 \).

In the following, we present some regularity conditions. Recall that we define \( g(y_i, x_i, \beta^*) \) and \( H \) in (3.10) and (3.6), respectively. Denote
\[ \Sigma = \mathbb{E}\{g(y_i, x_i, \beta^*)^{\otimes 2}\}, \quad H_{\alpha|\gamma} = H_{\alpha\alpha} - H_{\alpha\gamma}H_{\gamma\gamma}^{-1}H_{\gamma\alpha}. \]

**Assumption 4.1.** Assume that \( Y \) is subexponential which satisfies Definition 1.1, and \( \|X\|_\infty \leq m \) for a positive constant \( m \). Assume that \( c \leq \lambda_{\min}(\Sigma) \leq \lambda_{\max}(\Sigma) \leq c' \), and \( c \leq \lambda_{\min}(H) \leq \lambda_{\max}(H) \leq c' \), for some constants \( c, c' > 0 \).

It is easily seen that the subexponential condition holds for most commonly used GLMs in practice. Following \([37]\), we assume the bounded covariates for simplicity. It can be easily relaxed to the sub-Gaussian or subexponential assumptions. Note that \( \Sigma \) can be interpreted as the second moment of the Hájek projection, which approximates the asymptotic variance of \( \nabla \ell(\beta^*) \), and \( H_{\alpha|\gamma} \) is known as the partial information matrix for \( \alpha \) in the literature. This condition assumes that the
eigenvalues of $\Sigma$ and $H$ are lower and upper bounded by positive constants. They are standard regularity conditions even for low dimensional models.

The following main theorem establishes the asymptotic normality of the maximum directional likelihood estimator $\hat{\alpha}^P$. Let $s = \|\beta^*\|_0$ and $s_1 = \|w^*\|_0$, where $w^*$ is defined in (3.6).

**Theorem 4.1.** Under the semiparametric GLM in Definition 2.2 and Assumption 4.1, assume that $\hat{\beta}$ satisfies $\|\hat{\Delta}\|_2 = O_P(s \sqrt{\log d/n})$, $\|\hat{\Delta}\|_1 = O_P(s \sqrt{\log d/n})$, and $|\hat{\Delta}^T \nabla^2 \ell(\beta^*) \hat{\Delta}| = O_P(s \log d/n)$, where $\Delta = \hat{\beta} - \beta^*$. Given any small constant $\delta > 0$, it holds

$$
\lim_{n \to \infty} \frac{\max\{s, s_1\}^2 \cdot \log d}{n^{1/2-\delta}} = 0.
$$

Then with $\lambda_1 \times \log n \cdot \sqrt{\log d/n}$, we have

$$
n^{1/2}(\hat{\alpha}^P - \alpha^*) \rightsquigarrow N(0, 4\sigma^2 H_{\alpha|\gamma}^{-2})
$$

where $\sigma^2 = \Sigma_{\alpha\alpha} - 2w^*T \Sigma_{\gamma\alpha} + w^*T \Sigma_{\gamma\gamma} w^*$.\n
**Proof.** A detailed proof is provided in Appendix A. \qed

Our condition (4.1) essentially requires that $w^*$ and $\beta^*$ are sufficiently sparse such that the estimation errors of $w^*$ and $\beta^*$ and the approximation error in the Hájek projection are controllable. Similarly, under the GLM, [37] assumed that the inverse of the Fisher information matrix $\Omega = H^{-1}$ is sparse. Let $\Omega_{s\alpha}$ and $\Omega_{s\gamma}$ denote the columns of $\Omega$ corresponding to $\alpha$ and $\gamma$. To see the connections, consider the following block matrix inverse formula, $\Omega_{s\alpha} = H_{\alpha|\gamma}^{-1} \left(1, -H_{\alpha\gamma} H_{\gamma\gamma}^{-1}\right)^T$, where $H_{\alpha|\gamma} = H_{\alpha\alpha} - H_{\alpha\gamma} H_{\gamma\gamma}^{-1} H_{\gamma\alpha}$. Since $w^* = H^{-1}_{\gamma\gamma} w_{\gamma\alpha}$, we have $\|w^*\|_0 = \|\Omega_{s\alpha}\|_0 - 1$. Hence, our sparsity assumption on $w^*$ is implied by the sparsity of $\Omega$. Moreover, our results reveal that the sparsity of $\Omega_{s\gamma}$ is not needed for the inference on $\alpha$.

Under the GLM, [37] and [4] imposed the condition that $\max\{s, s_1\}^2 \cdot \log^k d = o(n)$ for some constant $k > 0$, which is weaker than our condition (4.1). This is mostly due to the technical differences between the composite likelihood derived by the chromatography approach (which has a U-statistic structure) and the likelihood of the generalized linear model.

We also note that, the rate of $\lambda_1$ agrees with the conventional $\sqrt{\log d/n}$ rate for tuning parameters up to a $\log n$ factor, due to the subexponential tail of the response variable $Y$. In particular, if $Y$ is bounded (e.g., 0–1 binary response), the $\log n$ factor can be eliminated so that we have $\lambda_1 \asymp \sqrt{\log d/n}$.

It is seen that our assumptions do not contain any type of minimal signal strength condition on the nonzero components of $\beta^*$. Therefore, unlike the oracle-type results in [11], variable selection consistency is not a priori for our approach and a valid p-value can be produced even if a covariate is not selected in the model.
Remark 3 (Estimation consistency). Note that Theorem 4.1 requires that the initial estimator \( \hat{\beta} \) satisfies 
\[ \| \hat{\beta} - \beta^* \|_2 = O_p(\sqrt{s \log d/n}), \quad \| \hat{\beta} - \beta^* \|_1 = O_p(s \sqrt{\log d/n}) \]
and 
\[ |(\hat{\beta} - \beta^*)^T \nabla^2 \ell(\beta^*)(\hat{\beta} - \beta^*)| = O_p(s \log d/n). \]
In high-dimensional settings, we can estimate \( \beta \) by maximizing the following penalized composite likelihood function with a generic penalty function \( p_\lambda(\cdot) \):

\[
4.2 \quad \hat{\beta} \in \text{argmax}_{\beta \in \mathbb{R}^d} \left\{ \ell(\beta) - \sum_{j=1}^d p_\lambda(\beta_j) \right\},
\]
where \( \lambda \geq 0 \) is a tuning parameter. In GLMs, [12, 21, 38] showed such conditions hold. We prove that the same conclusion holds for \( \hat{\beta} \) under the semiparametric GLM. To save space, we leave the detailed analysis of the finite sample estimation error bound of \( \hat{\beta} \) with both Lasso penalty and the nonconvex penalty to the Supplementary Material [29]. Here, we emphasize that our inferential framework allows general regularized estimators such as nonconvex penalty functions. Thus, it is more flexible than [37] based on inverting the Karush–Kuhn–Tucker condition for the Lasso estimator.

To apply Theorem 4.1 to construct confidence intervals, one needs to estimate the asymptotic variance \( \sigma^2 H_{\alpha^*|\gamma}^{-2} \), which depends on the unknown covariance matrix \( \Sigma \) and \( H_{\alpha^*|\gamma} \). Recall that such an estimator \( \hat{\Sigma} \) is given in (3.11). The following corollary justifies the validity of the confidence interval.

**Corollary 4.1.** Under the conditions in Theorem 4.1, the confidence interval
\[
\text{CI}_\xi = \{ \alpha \in \mathbb{R} : |\alpha - \hat{\alpha}^P| \leq 2 \cdot \hat{\sigma} \cdot H_{\alpha^*|\gamma}^{-1} \cdot \Phi^{-1}(1 - \xi/2)/n^{1/2} \}
\]
has the asymptotic coverage \( 1 - \xi \), that is, \( \lim_{n \to \infty} \mathbb{P}(\alpha^* \in \text{CI}_\xi) = 1 - \xi \).

**Proof.** A detailed proof is shown in the Supplementary Material [29]. \( \square \)

We note that the estimator \( \hat{\alpha}^P \) is not semiparametrically efficient, because not all information about \( \beta \) is retained in the statistical chromatography. Our numerical results seem to suggest that \( \hat{\alpha}^P \) is nearly as efficient as the estimator under the classical generalized linear model. Thus, our method gains model flexibility and computational efficiency without paying much price on the information loss.

Next, we prove the asymptotic distribution of the test statistic \( \Lambda_n \) and the validity of the maximum likelihood ratio test under the same conditions in Theorem 4.1 and Corollary 4.1.

**Theorem 4.2.** Under the conditions in Theorem 4.1 and \( \alpha^* = \alpha_0 \), then
\[
(4 \cdot \sigma^2)^{-1} \cdot H_{\alpha^*|\gamma} \cdot \Lambda_n \sim \chi_1^2.
\]
As before, to apply the theorem in practice, we replace $\sigma^2$ and $H_{\alpha | \gamma}$ with their estimators. The following corollary shows that under $H_0$, type I error of the test $\psi_{DLRT}(\xi)$ converges to the desired significance level $\xi$ and the p-value is asymptotically uniform.

**Corollary 4.2.** Suppose the conditions in Corollary 4.1 hold. Then

$$\lim_{n \to \infty} \mathbb{P}(\psi_{DLRT}(\xi) = 1 \mid H_0) = \xi \quad \text{and} \quad P_{DLRT} \rightsquigarrow \text{Uniform}[0, 1] \quad \text{under } H_0,$$

where $\psi_{DLRT}(\omega)$ is defined in (3.12) and $P_{DLRT} = 1 - \chi_1^2((4 \cdot \hat{\sigma}^2)^{-1} \cdot \hat{H}_{\alpha | \gamma} \cdot \Lambda_n)$ is the associated p-value.

**Proof.** A detailed proof is shown in the Supplementary Material [29].

Finally, we conclude this section with the following remarks on the extensions to missing data and multiple datasets inference. Due to the space constraint, we defer the detailed results to the Supplementary Material [29].

**Remark 4 (Missing data and multiple datasets inference).** In the missing data setup, as shown in equation (2.3), $Y$ given $X$ and $\delta = 1$ satisfies the semiparametric GLM with the same finite dimensional parameter $\beta$ and unknown function $f^m(\cdot)$. The inferential results in this section can be easily extended to the missing data setup; see the Supplementary Material [29] for details. In the multiple datasets inference setup, the sparsity patterns of the $d$-dimensional parameter $\beta_t^*$ in (1.2) are usually identical across $t = 1, \ldots, T$. To encourage the common sparsity of $\beta_t^*$ and meanwhile account for the heterogeneity of different datasets, we can use similar estimation procedures to (4.2) with the group Lasso penalty. In the Supplementary Material [29], we obtain the finite sample error bounds for parameter estimation and the corresponding inferential results. In particular, by establishing a new maximal inequality for U-statistic with unbounded kernels (i.e., Lemma F.2 of the Supplementary Material [29]), we prove that the group Lasso estimator attains faster rates of convergence than the Lasso estimator. This extends the results in linear models [22] to the more challenging semiparametric setting.

5. Numerical results. In this section, we provide synthetic and real data examples to back up the theoretical results.

5.1. Simulation studies. We conduct simulation studies to assess the finite sample performance of the proposed methods. We generate the outcomes from (1) the linear regression with the standard Gaussian noise or (2) the logistic regression, and the covariates from $N(0, \Sigma)$, where $\Sigma_{ij} = 0.6^{|i-j|}$. The true values of $\beta$
are $\beta_j^* = \mu$ for $j = 1, 2, 3$ and $\beta_j^* = 0$ for $j = 4, \ldots, d$. Thus, the cardinality of the support set of $\beta^*$ is $s = 3$. The sample size is $n = 100$, the number of covariates is $d = 200$ and the number of simulation replications is 500.

We calculate the $\ell_1$-regularized estimator $\hat{\beta}$ by using the `glmnet` package in R. In particular, we determine the regularization parameter $\lambda$ by minimizing the K-fold cross validated loss function,

$$CV(\lambda) = \sum_{k=1}^{K} \{ \ell(\hat{\beta}^{(-k)}_{\lambda}) - \ell^{(-k)}(\hat{\beta}^{(-k)}_{\lambda}) \},$$

where $\ell^{(-k)}$ stands for the loss function evaluated without the $k$th subset and similarly $\hat{\beta}^{(-k)}_{\lambda}$ stands for the regularized estimator derived without using the $k$th subset. In the simulation studies, we use 5-fold cross validation. The tuning parameter for the Dantzig selector $\lambda_1$ in (3.9) is chosen by $4\sqrt{\log(nd)/n}$. We find that the simulation results are not sensitive to the choice of $\lambda_1$. We only present the results with the Lasso penalty. Similar results are observed by using the folded concave penalty based on the LLA algorithm [12].

For the linear regression, we consider the directional likelihood ratio test (DLRT) and the Wald test based on the asymptotic normality of $\hat{\alpha}^P$, as well as the desparsifying method in [37, 41] and debias method in [15]. Both of these two methods are tailored for the linear regression with the $L_2$ loss and are optimal for confidence intervals and hypothesis testing. To examine the validity of our tests, we report their type I errors for the null hypothesis $H_0 : \beta_1 = \mu$ with various choices of $\mu \in [0, 1]$ at the 0.05 significance level. The results are summarized in Table 1. We find that, our Wald test and DLRT yield accurate type I errors, which are comparable to the desparsifying and debias methods. In addition, we also compare the powers of these tests. In particular, we test the null hypothesis $H_0 : \beta_1 = 0$, but increase $\mu$ from 0 to 1 in the data generating procedure. As shown in the left panel

</table>
of Figure 1, our Wald test and DLRT based on the semiparametric GLM are nearly as efficient as the desparsifying and debias methods. Such results show that the semiparametric GLM gains model flexibility by losing little inferential efficiency.

For the logistic model, we only consider the desparsifying method, because the debias method is not defined. As shown in Table 1, our proposed tests yield well controlled type I errors. Similarly, the power comparison for testing $H_0 : \beta_1 = 0$ in Figure 1 reveals that our tests under the more flexible semiparametric model are comparable to the desparsifying method. Moreover, the DLRT is more powerful than the remaining two tests, which demonstrates the numerical advantages of the likelihood ratio inference over the Wald-type tests. This observation is also consistent with the literature for low dimensional inference.

To further demonstrate the advantage of the proposed methods, we consider the data with missing values. Similar to the previous data generating procedures, we first simulate the original data $Y_i$ and $X_i$. Then, for the linear regression, we consider the following two scenarios to create missing values: (1) the response $Y_i$ is observed (i.e., $\delta_i = 1$) if and only if $Y_i \leq 0$; and (2) $Y_i$ is always observed if $Y_i \leq 0$ and observed with probability 0.2 if $Y_i > 0$, that is, $P(\delta_i = 1 \mid Y_i, X_i) = 1 - 0.8I(Y_i > 0)$. For the logistic regression, we also consider two scenarios to create missing values: (1) $P(\delta_i = 1 \mid Y_i, X_i) = 0.2 + 0.6Y_i$; and (2) $P(\delta_i = 1 \mid Y_i, X_i) = 0.2 + 0.8Y_i$. Since the desparsifying and debias methods are developed based on the assumption that no missing values exist, we consider the following two practical procedures for handling missing data on $Y$. The first approach is that we apply the desparsifying and debias methods directly to samples with $Y$ observed, which is known as the complete-case analysis. The second approach is that we apply these two methods to an imputed dataset. More specifically, for those samples with missing values on $Y$, we impute $Y$ by using the k-nearest neighbors method, implemented by the R function `impute.knn`. The type I errors are shown in Table 2. As expected, for the desparsifying and debias methods,
**Table 2**

Type I errors of the Wald test and directional likelihood ratio test (DLRT), the desparsifying method and debias method based on complete-case analysis (CC-) and imputation (Imp-) for linear and logistic regressions with missing data (selection bias) for $H_0: \alpha = \mu$, at the 0.05 significance level, where $\mu = 0.10, \ldots, 0.25$

The type I errors of the complete-case analysis are far from the 0.05 significance level. Although the imputation method shows some advantages over the complete-case analysis, similar patterns are observed. Therefore, in the presence of missing data, the existing methods cannot produce any result that is statistically reliable. In contrast, the type I errors based on the proposed tests are well controlled, and they are robust to the missing data and selection bias. The same conclusion holds under all simulation scenarios.

In summary, our proposed testing procedures under the semiparametric GLM are as competitive as the existing methods even if the assumed model is correct. More importantly, in the presence of missing data or selection bias, the proposed methods significantly outperform the existing ones.

### 5.2. Analysis of gene expression data

In this section, we apply the proposed tests to analyze the AGEMAP (Atlas of Gene Expression in Mouse Aging Project) gene expression data [40]. The dataset contains the expression values for 296 genes...
Significant genes selected by the Wald and directional likelihood ratio tests under the semiparametric GLM, the desparsifying method and debias method based on complete-case analysis (CC- and imputation (Imp-) for the gene expression data. Here, M% samples are missing.

belonging to the mouse vascular endothelial growth factor (VEGF) signaling pathway. The sample size is \( n = 40 \). Among these 296 genes, we are interested in identifying genes that are significantly associated with the target gene Casp9. Thus, we treat the gene Casp9 as the response and the remaining 295 genes as covariates.

Since no missing value presents, we directly apply the desparsifying and debias methods to test \( H_0 : \beta_j = 0 \) for each \( 1 \leq j \leq 295 \), under the linear model assumption. Similarly, we can assume that the gene Casp9 given the remaining variables follows the semiparametric GLM and the proposed Wald and likelihood ratio tests can be applied. To take into account of the multiplicity of tests, we use the step-down method in the R function \( \text{p.adjust} \) to adjust the p-values. At the 0.05 significance level, all these four methods claim that gene Cdc42 is significant; see the first row of Table 3. This suggests that our tests are as effective as those existing procedures when there are no missing values.

To further illustrate the advantage of our methods in the presence of missing data, we create missing values for the outcome variable \( Y_i \). More specifically, if \( Y_i \) is among the top \( M\% \) samples, where \( M = 0, 15, 25 \) and 35, we remove the values of \( Y_i \). Here, \( M = 0 \) means no missing data is created. This corresponds to the analysis of the original complete data. Similar to that in the simulation studies, the considered missing data mechanism depends on the unobserved values, which makes the analysis challenging.

The results are shown in Table 3, where the results based on the original complete data (\( M = 0 \)) can be used as a benchmark. Based on the incomplete dataset, after the same adjustment for p-values, our Wald and likelihood ratio tests still select gene Cdc42, which are consistent with the results based on the original data. This pattern is preserved, even after 35% data are removed. For the desparsifying and debias methods, similar to the simulation studies, we can either apply them to those samples with only complete data (complete-case analysis) or the full data created by the imputation method. In particular, the CC-Desparsity and the CC-Debias methods consistently select no genes, when there exist missing data. This seems to suggest a lack of power for the existing methods based on the complete-case analysis. In addition, Imp-Desparsity tends to select very different genes at
different levels of missing data percentage. They are all different from the benchmark gene Cdc42. Our analysis suggests that the presence of missing values can dramatically change the results of Imp-Desparsity. Finally, Imp-Debias performs similar to CC-Debias and tends to have low powers.

In conclusion, the existing methods based on the imputation methods or complete cases are either very sensitive to the missing data or have low powers. On the other hand, the proposed tests are quite robust and potentially more reliable in the presence of missing data.

6. Discussion. In this paper, we propose a new likelihood ratio inference framework for high-dimensional semiparametric generalized linear models. The proposed model is semiparametric in that the base measure function $f(\cdot)$ is unspecified. This offers extra flexibility to handle the problems with missing data, selection bias and heterogeneity. We note that the proposed model is different from many standard semiparametric models such as the partially linear model. Although in this paper we only consider the likelihood ratio inference for the semiparametric GLM, similar inferential methods can be applied to more general high-dimensional semiparametric models. This is an interesting direction to explore in the future.

Another future direction is to develop the joint confidence intervals for the entire $d$-dimensional parameter $\beta^*$. Under the GLM, [4] constructed the joint confidence intervals based on a multiplier bootstrap method for approximating maximum of sums of independent high-dimensional random vectors [9]. Under the proposed semiparametric GLM, the gradient of the composite log-likelihood has a U-statistic structure. To construct joint confidence intervals, it may require to extend the high-dimensional multiplier bootstrap method based on sums of independent random vectors to U-statistics. Such extensions are worthy of further investigation.

APPENDIX A: PROOF OF MAIN RESULTS

In this Appendix, we give the proof of Theorem 4.1. The proofs of the remaining results, including Corollary 4.1, and Theorem 4.2 are deferred to the Supplementary Material [29].

We define an unbiased score function as $S(\beta^*) := \nabla_\alpha \ell(\beta^*) - w^* \nabla_\gamma \ell(\beta^*)$, which plays an important role in the proof. The proof of Theorem 4.1 has three steps. First, we show that the first derivative of $\hat{\ell}(\alpha)$ approximates $S(\beta^*)$. Second, we apply the central limit theorem for a linear combination of high-dimensional U-statistics to conclude the asymptotic normality of $S(\beta^*)$. Finally, we show that the negative Hessian of $\hat{\ell}(\alpha)$ approximates $H_{\alpha|\gamma}$. For notational simplicity, denote $M := \max_{1 \leq i < j \leq n} \| (y_i - y_j) \cdot (x_i - x_j) \|_{\infty}$. By Assumption 4.1, we have $M = O_p(\log n)$.

Step 1: Show the convergence of $\hat{\ell}(\alpha^*)$. Define $\hat{\gamma}(\alpha) := \hat{\gamma} + (\alpha - \alpha) \hat{w}$ and $\hat{\Delta}_y = \hat{\gamma}(\alpha^*) - \gamma^*$. Moreover, recall that $S(\beta^*) := \nabla_\alpha \ell(\beta^*) - w^* \nabla_\gamma \ell(\beta^*)$. By
the chain rule and mean value theorem, we have
\begin{equation}
\ell'(\alpha^*) = \nabla_{\alpha} \ell(\alpha^*, \hat{\gamma}(\alpha^*)) - \hat{w}^T \nabla_{\gamma} \ell(\alpha^*, \hat{\gamma}(\alpha^*)) = S(\beta^*) + I_1 + I_2,
\end{equation}
where \( I_1 := (w^* - \hat{w})^T \nabla_{\gamma} \ell(\beta^*) \) and \( I_2 := \{ \nabla_{\alpha} \ell(\alpha^*, \hat{\gamma}) - \hat{w}^T \nabla_{\gamma} \ell(\alpha^*, \hat{\gamma}) \} \hat{\Delta}_{\gamma} \).
Here, \( \hat{\gamma} \) and \( \gamma \) are intermediate values between \( \gamma^* \) and \( \hat{\gamma}(\alpha^*) \). Thus, the first step of the proof reduces to controlling the two terms \( I_1 \) and \( I_2 \) in (A.1). In particular, to bound \( I_1 \), we need the following Lemma A.1 to bound \( \| \hat{w} - w^* \|_1 \) and Lemma A.2 to bound \( \| \nabla \ell(\beta^*) \|_\infty \), respectively.

**Lemma A.1.** Under the conditions in Theorem 4.1,
\[
\| \hat{w} - w^* \|_1 = O_P\left( M(s + s_1) \cdot \sqrt{\frac{\log d}{n}} \right).
\]

**Lemma A.2.** Assume that Assumption 4.1 holds. Then, for any \( C'' > 0 \), we have \( \| \nabla \ell(\beta^*) \|_\infty \leq C'' \cdot \sqrt{\log d/n} \), with probability at least
\begin{equation}
1 - 2 \cdot d \cdot \exp\left[ -\min\left\{ \frac{C^2 \cdot C''^2}{2^9 \cdot C' \cdot m} \cdot \frac{\log d}{n} , \frac{C \cdot C''}{2^5 \cdot C' \cdot m} \cdot \sqrt{\frac{\log d}{n}} \right\} \cdot k \right],
\end{equation}
where \( k = \lfloor n/2 \rfloor \), and \( C, C' \) are defined in Definition 1.1.

**Proof.** To prove Lemma A.2, the key is to prove a new concentration inequality for U-statistics with subexponential kernel functions. In particular, the following lemma allows the kernel function to be unbounded, which is more general than most of existing concentration results for U-statistics with bounded kernels, such as Theorem 4.1.13 in [10]. The following result can be of independent interest, whose proof is shown in the Supplementary Material [29].

**Lemma A.3.** Let \( X_1, \ldots, X_n \) be independent random variables. Consider the following U-statistics of order \( m \),
\[
U_n = \binom{n}{m}^{-1} \sum_{i_1 < \cdots < i_m} u(X_{i_1}, \ldots, X_{i_m}),
\]
where the summation is over all \( i_1 < \cdots < i_m \) selected from \( \{1, \ldots, n\} \) and \( \mathbb{E}[u(X_{i_1}, \ldots, X_{i_m})] = 0 \) for all \( i_1 < \cdots < i_m \). Assume that the kernel function \( u(X_{i_1}, \ldots, X_{i_m}) \) is symmetric in the sense that \( u(X_{i_1}, \ldots, X_{i_m}) \) is independent of the order of \( X_{i_1}, \ldots, X_{i_m} \). If there exist constants \( L_1 \) and \( L_2 \), such that
\begin{equation}
\mathbb{P}(|u(X_{i_1}, \ldots, X_{i_m})| \geq x) \leq L_1 \cdot \exp(-L_2 \cdot x),
\end{equation}
for all \( i_1 < \cdots < i_m \) and all \( x \geq 0 \), then
\[
\mathbb{P}(|U_n| \geq x) \leq 2 \cdot \exp\left[ -\min\left\{ \frac{L_2^2 \cdot x^2}{8 \cdot L_1^2}, \frac{L_2 \cdot x}{4 \cdot L_1} \right\} \cdot k \right],
\]
where \( k = \lfloor n/m \rfloor \) is the largest integer less than \( n/m \).
Given the above lemma, we need to verify that the kernel function \( h_{ij}(\beta^*) \) has mean 0, where

\[
(A.4) \quad h_{ij}(\beta) = \frac{R_{ij}(\beta) \cdot (y_i - y_j) \cdot (x_i - x_j)}{1 + R_{ij}(\beta)},
\]

and it satisfies \((A.3)\). To show \( \mathbb{E}[h_{ij}(\beta^*)] = 0 \), let \( \Xi_{ij} \) denote the event \( \{(Y_i^L, Y_j^R) = (y_i, y_j), X_i = x_i, X_j = x_j\} \). By \((3.3)\), the conditional distribution of \( Y_i \) and \( Y_j \) given \( \Xi_{ij} \) follows a binomial distribution,

\[
(A.5) \quad \mathbb{P}(Y_i = y_i, Y_j = y_j \mid \Xi_{ij}; \beta) = \left[ 1 + R_{ij}(\beta) \right]^{-1},
\]

and \( \mathbb{P}(Y_i = y_i, Y_j = y_j \mid \Xi_{ij}; \beta) = R_{ij}(\beta)/[1 + R_{ij}(\beta)] \). According to this binomial distribution, the conditional expectation of \( h_{ij}(\beta^*) \) given \( \Xi_{ij} \) is

\[
\mathbb{E}[h_{ij}(\beta^*) \mid \Xi_{ij}; \beta^*] = \frac{R_{ij}(\beta^*)(y_i - y_j)(x_i - x_j)}{1 + R_{ij}(\beta^*)} \mathbb{P}(Y_i = y_i, Y_j = y_j \mid \Xi_{ij}; \beta^*) + \frac{R_{ij}^{-1}(\beta^*)(y_j - y_i)(x_i - x_j)}{1 + R_{ij}^{-1}(\beta)} \mathbb{P}(Y_i = y_j, Y_j = y_i \mid \Xi_{ij}; \beta^*).
\]

By plugging \((A.5)\) into above equation, it is easy to verify that \( \mathbb{E}[h_{ij}(\beta^*) \mid \Xi_{ij}] = 0 \). Finally, \( \mathbb{E}[h_{ij}(\beta^*)] = \mathbb{E}[\mathbb{E}[h_{ij}(\beta^*) \mid \Xi_{ij}]] = 0 \). Next, we verify the kernel function satisfies \((A.3)\). Since \( R_{ij}(\beta) > 0 \) and \( \max_{ij} |x_{ij}| \leq m \), we have

\[
\|h_{ij}(\beta^*)\|_{\infty} \leq \|y_i - y_j\| \cdot \|x_i - x_j\|_{\infty} \leq 2m \cdot |y_i - y_j|.
\]

By the subexponential tail condition on \( y_i \), for any \( x > 0 \) and \( k = 1, \ldots, d \),

\[
\mathbb{P}([|h_{ij}(\beta^*)|_k > x]) \leq \mathbb{P}(|y_i - y_j| > (2m)^{-1}x) \leq 2C' \exp\{-C'(4m)^{-1}x\}.
\]

Then we apply Lemma \(A.3\) with \( k = \lfloor n/2 \rfloor \) to complete the proof. □

Hence, by Lemma \(A.1\) and Lemma \(A.2\), we can show that

\[
|I_1| \leq \|w^* - \hat{w}\|_1 \|\nabla_y \ell(\beta^*)\|_{\infty} = \mathcal{O}_\mathbb{P}\left( M(s + s_1) \cdot \sqrt{\frac{\log d}{n}} \cdot \sqrt{\frac{\log d}{n}} \right) = o_\mathbb{P}\left( \frac{1}{\sqrt{n}} \right),
\]

where the last step follows by the conditions in Theorem \(4.1\). We further separate \( I_2 \) into the following terms: \( I_2 = I_{21} + I_{22} + I_{23} \), where \( I_{21} = \|\nabla_{\alpha y} \ell(\beta^*) - \hat{w}^T \nabla_{yy} \ell(\beta^*)\|_{\Delta_y} \), \( I_{22} = \|\nabla_{\alpha y} \ell(\beta^*) - \nabla_{\alpha y} \ell(\alpha^*, \hat{y})\|_{\Delta_y} \) and \( I_{23} = \|\hat{w}^T \nabla_{yy} \ell(\beta^*) - \nabla_{yy} \ell(\alpha^*, \hat{y})\|_{\Delta_y} \). To control the three terms, we first need to bound \( \|\Delta_y\|_1 \). By the conditions in Theorem \(4.1\), we have \( \|\hat{y} - y^*\|_1 = \mathcal{O}_\mathbb{P}(s/\sqrt{\log d/n}) \) and \( |\hat{\alpha} - \alpha^*| = \mathcal{O}_\mathbb{P}(s^{1/2}/\sqrt{\log d/n}) \). Moreover, by the Cauchy–Schwarz inequality, it holds that \( \|w^*\|_1 \leq \sqrt{s_1} \|w^*\|_2 \leq \sqrt{s_1} \|H_{yy}^{-1} H_{yy}^T\|_2 \leq \mathcal{O}_\mathbb{P}(\sqrt{s}/\sqrt{n}) \).
\( \sqrt{\frac{s}{t}} \lambda_{\min}(H)^{-1} \lambda_{\max}(H) \leq \sqrt{\frac{s}{t}} c^{-1} c' \), where the last inequality is by Assumption 4.1. Therefore,

\[
\| \widehat{\Delta}_y \|_1 \leq \| \widehat{y} - y^* \| + |\widehat{\alpha} - \alpha^*| \| \widehat{w} \|_1 = O_P \left( \max\{s, s_1\} \sqrt{\frac{\log d}{n}} \right),
\]

where we used the fact that \( \| \widehat{w} \|_1 = \| w^* \|_1 + o_P(1) = O_P(s_1^{1/2}) \). To control the three terms in \( I_2 \), the key step is to quantify the smoothness of the Hessian matrix \( \nabla^2 \ell(\alpha^*, y) \) in a small neighborhood of \( y^* \).

**Lemma A.4.** Under the conditions in Theorem 4.1, for any deterministic sequence \( \delta_n \) such that \( M \cdot \delta_n = o(1) \), we have

\[
\sup_{\| \beta - \beta^* \|_1 \leq \delta_n} \| \nabla^2 \ell(\beta) - \nabla^2 \ell(\beta^*) \|_\infty = O_P(M \cdot \delta_n),
\]

where \( M := \max_{1 \leq i < j \leq n} \| (y_i - y_j) \cdot (x_i - x_j) \|_\infty \).

**Proof.** Let \( w_{ij} = \exp\{- (y_i - y_j) \cdot \Delta^T (x_i - x_j) \} \), where \( \Delta = \beta - \beta^* \). By definition, \( R_{ij}(\beta) = R_{ij}(\beta^*) \cdot w_{ij} \). Thus,

\[
\nabla^2 \ell(\beta) = -\left( \frac{n}{2} \right)^{-1} \sum_{1 \leq i < j \leq n} \frac{u_{ij} \cdot R_{ij}(\beta^*) \cdot (y_i - y_j)^2 \cdot (x_i - x_j)^{\otimes 2}}{(1 + R_{ij}(\beta^*))^2},
\]

where \( u_{ij} = w_{ij} \cdot (1 + R_{ij}(\beta^*))^2 (1 + w_{ij} \cdot R_{ij}(\beta^*))^{-2} \). Note that if \( w_{ij} \geq 1 \), then \( (1 + R_{ij}(\beta^*))^2 / (1 + w_{ij} \cdot R_{ij}(\beta^*))^2 \leq 1 \). On the other hand, if \( w_{ij} \leq 1 \),

\[
\frac{(1 + R_{ij}(\beta^*))^2}{(1 + w_{ij} \cdot R_{ij}(\beta^*))^2} \leq \frac{(1 + R_{ij}(\beta^*))^2}{w_{ij}^2 (1 + R_{ij}(\beta^*))^2} = \frac{1}{w_{ij}^2}.
\]

Thus, \( u_{ij} \leq \max\{w_{ij}, w_{ij}^{-1} \} \). Therefore, for any \( 1 \leq s, t \leq d \),

\[
| \nabla^2_{st} \ell(\beta) - \nabla^2_{st} \ell(\beta^*) |
\]

\[
= \left( \frac{n}{2} \right)^{-1} \sum_{i < j} R_{ij}(\beta) (y_i - y_j)^2 (x_{is} - x_{js}) (x_{it} - x_{jt}) (u_{ij} - 1) \]

\[
\leq 2^{-1} | \nabla^2_{ss} \ell(\beta^*) + \nabla^2_{tt} \ell(\beta^*) | \max_{i < j} | \max\{w_{ij}, w_{ij}^{-1} \} - 1 |.
\]

By Hölder’s inequality, we have

\[
\sup_{\| \beta - \beta^* \|_1 \leq \delta_n} \max_{1 \leq i < j} | (y_i - y_j) \cdot \Delta^T (x_i - x_j) | \leq M \cdot \| \Delta \|_1 = O_P(M \cdot \delta_n) = o_P(1),
\]

and \( \sup_{\| \beta - \beta^* \|_1 \leq \delta_n} \max_{i < j} | \max\{w_{ij}, w_{ij}^{-1} \} - 1 | = O_P(M \cdot \delta_n) \). Thus, by (A.6),

\[
\sup_{\| \beta - \beta^* \|_1 \leq \delta_n} \| \nabla^2 \ell(\beta) - \nabla^2 \ell(\beta^*) \|_\infty \lesssim \{ \| \nabla^2 \ell(\beta^*) + H \|_\infty + \| H \|_\infty \} M \delta_n.
\]
By Assumption 4.1, \( \|H\|_\infty \) is bounded. It remains to control \( \|\nabla^2 \ell(\beta^*) + H\|_\infty \). Let \( \tilde{r}_{ij} = T_{ij} - E(T_{ij}) \), where

\[
T_{ij} = \frac{R_{ij}(\beta^*) \cdot (y_i - y_j)^2 \cdot (x_i - x_j)^2}{(1 + R_{ij}(\beta^*))^2}
\]

Then \( \nabla^2 \ell(\beta^*) + H = -\frac{2}{n(n-1)} \cdot \sum_{i<j} \tilde{r}_{ij} \) is a mean-zero second-order U-statistic with kernel function \( \tilde{r}_{ij} \). For any \( 1 \leq a, b \leq d \), \( \tilde{r}_{ij} \) satisfies \( \| \tilde{r}_{ij} \|_{(a,b)} \leq 2 \cdot M^2 \). The Hoeffding inequality yields, for any \( x > 0 \),

\[
\mathbb{P}(\| \nabla^2 \ell(\beta^*) + H \|_{a,b} > x) \leq 2 \cdot \exp\left(-\frac{k \cdot x^2}{8 \cdot M^4}\right),
\]

where \( k = \lfloor n/2 \rfloor \). Taking \( x = M^2 \sqrt{\log d / n} \), by union bound, we get with high probability, \( \| \nabla^2 \ell(\beta^*) + H\|_\infty \leq M^2 \sqrt{\log d / n} \). □

Now we consider these three terms in \( I_2 \) one by one. For \( I_{21} \), by Lemmas A.1 and C.2 in the Supplementary Material [29],

\[
I_{21} \leq \| \nabla^2_{\alpha\gamma} \ell(\beta^*) - w^T \nabla^2_{\gamma\gamma} \ell(\beta) \|_{\infty} \| \hat{\Delta}_Y \|_1 + \| \hat{\Delta}_Y - \mathbb{E} \| \nabla^2_{\gamma\gamma} \ell(\beta^*) \|_{\infty} \| \hat{\Delta}_Y \|_1
\]

\[
= O_P\left(M \cdot \max\{s, 1\} \cdot \frac{\log d}{n} + M \cdot \max\{s, 1\}^2 \cdot \frac{\log d}{n}\right) = o_P\left(\frac{1}{\sqrt{n}}\right),
\]

where the last step follows from the scaling condition (4.1). Now, we consider \( I_{22} \). By Lemma A.4 and the fact that \( \| \mathbb{Y} - \mathbb{Y}^* \|_1 \leq \| \hat{\Delta}_Y \|_1 = O_P(\max\{s, 1\} \cdot \sqrt{\log d / n}) \), we have

\[
I_{22} \leq \left\| \nabla^2_{\alpha\gamma} \ell(\beta^*) - \nabla^2_{\alpha\gamma} \ell(\alpha^*, \mathbb{Y}) \right\|_{\infty} \| \hat{\Delta}_Y \|_1
\]

\[
= O_P\left(M \cdot \max\{s, 1\}^2 \cdot \frac{\log d}{n}\right) = o_P\left(\frac{1}{\sqrt{n}}\right),
\]

where the last equality follows from the scaling condition (4.1). Following the similar arguments as in the proof of Lemma A.4, we can prove that

(A.7) \( I_{23} \leq C \left( M \cdot \max\{s, 1\} \cdot \sqrt{\frac{\log d}{n}} \right) \cdot |\hat{\mathbb{W}}^T \nabla^2_{\gamma\gamma} \ell(\beta^*) \hat{\Delta}_Y |. \)

By Lemma A.1 and the similar argument to the proof of Lemma C.2,

\[
|\hat{\mathbb{W}}^T \nabla^2_{\gamma\gamma} \ell(\beta^*) \hat{\Delta}_Y | \leq |w^T \nabla^2_{\gamma\gamma} \ell(\beta^*) \hat{\Delta}_Y | + |(\hat{\mathbb{W}} - w^T) \nabla^2_{\gamma\gamma} \ell(\beta^*) \hat{\Delta}_Y |
\]

\[
= O_P\left(\max\{s, 1\} \cdot \sqrt{\frac{\log d}{n}} + M \cdot \max\{s, 1\}^2 \cdot \frac{\log d}{n}\right).
\]

Together with (A.7), we have

\[
I_{23} = O_P\left(M \cdot \max\{s, 1\}^2 \cdot \frac{\log d}{n}\right) = o_P\left(\frac{1}{\sqrt{n}}\right).
\]
Thus, we have proved the rate of convergence of \( n^{1/2} |\hat{\ell}(\alpha^*) - S(\beta^*)| \), that is,  
\[
(A.8) \quad n^{1/2} \cdot |\hat{\ell}(\alpha^*) - S(\beta^*)| = O_P\left(M \cdot \max\{s, s_1\}^2 \cdot \frac{\log d}{\sqrt{n}}\right) = o_P(1).
\]

**Step 2:** Characterize the limiting distribution of \( S(\beta^*) \). We provide the following lemma on the central limit theorem for U-statistics with increasing dimensions.

**Lemma A.5.** Under Assumption 4.1, for any \( b \in \mathbb{R}^d \) with \( \|b\|_2 = 1 \), if \( \tilde{s}^{-1/2} \cdot n^{-1/2} \cdot M^3 = o_P(1) \), then  
\[
\frac{\sqrt{n}}{2} \cdot (b^T \Sigma b)^{-1/2} \cdot b^T \nabla \ell(\beta^*) \rightsquigarrow N(0, 1).
\]

**Proof.** The lemma is proved by using the Hoeffding’s decomposition:  
\[
\frac{\sqrt{n}}{2} \cdot (b^T \Sigma b)^{-1/2} \cdot b^T \nabla \ell(\beta^*) = (b^T \Sigma b)^{-1/2} \frac{1}{\sqrt{n}} \sum_{i=1}^n b^T g(y_i, x_i, \beta^*)
+ \frac{\sqrt{n}}{2} (b^T \Sigma b)^{-1/2} b^T \{ \nabla \ell(\beta^*) - \hat{U}_n \},
\]
where \( g(y_i, x_i, \beta^*) \) and \( \hat{U}_n \) are defined in (3.10). We can verify that the Lyapunov central limit theorem for independent random variables can be applied for the first term under the assumption that \( s_1 = o(n^{1/3 - \delta}) \). The remaining proof requires more careful calculation of the moment of approximation error \( b^T (\nabla \ell(\beta^*) - \hat{U}_n) \) in the Hájek projection, because here we allow the intrinsic dimension \( \tilde{s} \) to scale with \( n \). We defer the detailed proof to the Supplementary Material [29]. \( \square \)

Since \( S(\beta^*) \) is a sparse linear combination of the U-statistic \( \nabla \ell(0, y^*) \) and \( \|w^*\|_2 = s_1 \), with \( b = (1, -w^{*T})^T \), Lemma A.5 implies that  
\[
(A.9) \quad n^{1/2} S(\beta^*)/(2\sigma) \rightsquigarrow N(0, 1).
\]

**Step 3:** Show the convergence of \( \hat{\ell}''(\tilde{\alpha}) \) for any \( \tilde{\alpha} \) between \( 0 \) and \( \tilde{\alpha}^P \). We now show that \( |\hat{\ell}''(\tilde{\alpha}) + H_{\tilde{\alpha}|\gamma}| = o_P(1) \). By chain rule, we have  
\[
(A.10) \quad \hat{\ell}''(\tilde{\alpha}) = \nabla^2_{\tilde{\alpha} \tilde{\alpha}} \ell(\tilde{\alpha}, \tilde{\gamma}(\tilde{\alpha})) - 2 \nabla^2_{\tilde{\alpha} \gamma} \ell(\tilde{\alpha}, \tilde{\gamma}(\tilde{\alpha}))^T \hat{\omega} + \hat{\omega}^T \nabla^2_{\gamma \gamma} \ell(\tilde{\alpha}, \tilde{\gamma}(\tilde{\alpha}))^T \hat{\omega}
= (1, -\hat{\omega}^T) \nabla^2 \ell(\tilde{\alpha}, \tilde{\gamma}(\tilde{\alpha}))(1, -\hat{\omega}^T)^T.
\]
We then decompose \( \hat{\ell}''(\tilde{\alpha}) + H_{\tilde{\alpha}|\gamma} \) into two terms, namely,  
\[
\hat{\ell}''(\tilde{\alpha}) + H_{\tilde{\alpha}|\gamma} = \left[ \hat{\ell}''(\tilde{\alpha}) - (1, -\hat{\omega}^T) \nabla^2 \ell(\beta^*)(1, -\hat{\omega}^T)^T \right]
\]
\[
(A.11) \quad + \left[ (1, -\hat{\omega}^T) \nabla^2 \ell(\beta^*)(1, -\hat{\omega}^T)^T + H_{\tilde{\alpha}|\gamma} \right]
:= I_3 + I_4.
\]
Let $\tilde{\Delta} = (\tilde{\alpha}, \tilde{\gamma}(\tilde{\alpha})^T)^T - \beta^*$. We have

$$\|\tilde{\Delta}\|_1 \leq |\tilde{\alpha} - \alpha^*| + \|\tilde{\gamma} - \gamma^*\|_1 + |\tilde{\alpha} - \tilde{\alpha}||\tilde{\mathbf{w}}||_1.$$  

To control $|\tilde{\alpha} - \alpha^*|$, we need a bound on the rate of convergence of the post-regularization estimator $\hat{\alpha}^P - \alpha^*$. The following lemma serves our purpose.

**Lemma A.6.** Under the conditions in Theorem 4.1, we have

$$|\hat{\alpha}^P - \alpha^*| = O_P\left(\sqrt{\frac{\log n}{n}}\right).$$

By Lemma A.6, we have $|\tilde{\alpha} - \alpha^*| \leq |\hat{\alpha}^P - \alpha^*| = O_P(\sqrt{\log n/n})$. Moreover, we have $\|\tilde{\gamma} - \gamma^*\|_1 = O_P(s \cdot \sqrt{\log d/n})$, $\|\tilde{\mathbf{w}}\|_1 = \|\mathbf{w}^*\|_1 + o_P(1)$ and that

$$|\tilde{\alpha} - \tilde{\alpha}| \leq |\tilde{\alpha} - \alpha^*| + |\hat{\alpha} - \alpha^*| = O_P\left(\sqrt{\frac{s \log(d \vee n)}{n}}\right).$$

Putting together the above results and by (A.12), we conclude that $\|\tilde{\Delta}\|_1 = O_P(\max\{s, s_1\} \cdot \sqrt{\log(d \vee n)/n})$.

For the first term in (A.11), similar to the proof of Lemma A.4, we get

$$|I_3| \leq C \left(M \cdot \max\{s, s_1\} \cdot \sqrt{\frac{\log(d \vee n)}{n}}\right) \cdot |\hat{\mathbf{v}}^T \nabla^2 \ell(\beta^*)\hat{\mathbf{v}}|,$$

where $\hat{\mathbf{v}} = (1, \hat{\mathbf{w}}^T)^T$. Let $\mathbf{v}^* = (1, \mathbf{w}^*^T)^T$. By Lemma A.1 and Lemma C.2,

$$|\hat{\mathbf{v}}^T \nabla^2 \ell(\beta^*)\hat{\mathbf{v}}| \leq |\mathbf{v}^*^T \nabla^2 \ell(\beta^*)\mathbf{v}^*| + 2|\hat{\mathbf{v}} - \mathbf{v}^*|^T \nabla^2 \ell(\beta^*)\mathbf{v}^*|$$

$$+ |(\hat{\mathbf{v}} - \mathbf{v}^*)^T \nabla^2 \ell(\beta^*)(\hat{\mathbf{v}} - \mathbf{v}^*)|$$

$$\leq |\mathbf{v}^*^T \mathbf{H}\mathbf{v}^*| + o_P(1).$$

Therefore, we conclude that

$$|I_3| = O_P(M \cdot \max\{s, s_1\} \cdot \sqrt{\log(d \vee n)/n}) = o_P(1).$$

We now focus on $I_4$, which can be decomposed into the following terms: $I_4 = I_{41} - 2I_{42} + I_{43}$, where $I_{41} = \nabla^2_{\alpha \ell}(\beta^*) + H_{\alpha \alpha}, I_{42} = \hat{\mathbf{w}}^T \nabla^2_{\mathbf{w} \ell}(\beta^*) + \mathbf{w}^T H_{\mathbf{w} \mathbf{w}}$ and $I_{43} = \hat{\mathbf{w}}^T \nabla^2_{\mathbf{w} \ell}(\beta^*)\hat{\mathbf{w}} + \mathbf{w}^T H_{\mathbf{w} \mathbf{w}}\mathbf{w}^*$. By the proof of Lemma A.4, we have $\|\nabla^2 \ell(\beta^*) + \mathbf{H}\|_\infty = O_P(M^2 \cdot \sqrt{\log d/n})$. Hence, $I_{41} = O_P(M^2 \cdot \sqrt{\log d/n}) = o_P(1)$. For the second term, it holds that $I_{42} = \hat{\mathbf{w}}^T (\nabla^2_{\mathbf{w} \ell}(\beta^*) + H_{\mathbf{w} \mathbf{w}}) - (\hat{\mathbf{w}} - \mathbf{w}^*)^T H_{\mathbf{w} \mathbf{w}}$. We have $|\hat{\mathbf{w}}^T (\nabla^2_{\mathbf{w} \ell}(\beta^*) + H_{\mathbf{w} \mathbf{w}})| \leq \|\hat{\mathbf{w}}\|_1 \|\nabla^2_{\mathbf{w} \ell}(\beta^*) + H_{\mathbf{w} \mathbf{w}}\|_\infty = O_P(M^2 \cdot \sqrt{s_1 \log d/n})$, and $|((\hat{\mathbf{w}} - \mathbf{w}^*)^T H_{\mathbf{w} \mathbf{w}}) - (\hat{\mathbf{w}} - \mathbf{w}^*\|_1 \|H_{\mathbf{w} \mathbf{w}}\|_\infty = o_P(1)$.
Therefore, we conclude that $|I_{42}| = o_P(1)$. For the term $I_{43}$, we apply similar arguments to get $I_{43} = O_P(M(s_1 + s)\sqrt{\log d/n}) = o_P(1)$. Hence, we conclude that $I_4 = o_P(1)$. Together with (A.14), this implies

\begin{equation}
(A.15) \quad \left| \hat{c}''_n(\alpha) + H_{\alpha|y} \right| = o_P(1).
\end{equation}

Given (A.8), (A.9), (A.15), we now wrap up the whole proof. By first-order optimality condition, we have $\hat{c}'(\hat{\alpha}^P) = 0$. Applying mean-value theorem, we get

\begin{equation}
(A.16) \quad \hat{\alpha}^P - \alpha^* = \hat{c}''(\bar{\alpha})^{-1} \hat{c}'(\alpha^*).
\end{equation}

Finally, combining (A.16), (A.8), (A.9), (A.15) and applying Slutsky’s theorem, we have $n^{1/2}(\hat{\alpha}^P - \alpha^*) = -H_{\alpha|y}^{-1} \cdot n^{1/2} S(\beta^*) + o_P(1)$. We complete the proof of Theorem 4.1.

**Acknowledgments.** We thank the Editor, Associate Editor and two referees for their helpful comments, which significantly improves the presentation of this paper. We are also very grateful to Professor Cun-Hui Zhang for sharing his 2011 Oberwolfach report on statistical inference for high-dimensional data. We also thank Nancy Reid and Jing Qin for insightful comments.

**SUPPLEMENTARY MATERIAL**

Supplement for “A likelihood ratio framework for high-dimensional semiparametric regression” (DOI: 10.1214/16-AOS1483SUPP; .pdf). The supplementary material contain additional technical details, simulation results and proofs.

SUPPLEMENTARY MATERIALS TO “A LIKELIHOOD RATIO FRAMEWORK FOR HIGH DIMENSIONAL SEMIPARAMETRIC REGRESSION”

BY YANG NING* TIANQI ZHAO† AND HAN LIU†

Cornell University* and Princeton University†

This document contains supplementary appendices of the paper “A Likelihood Ratio Framework for High Dimensional Semiparametric Regression” authored by Yang Ning, Tianqi Zhao and Han Liu. It is organized as follows. Appendix B contains the additional proofs of main results in the main paper. Appendix C contains the proofs of technical lemmas used in the main paper. Appendix D contains the parameter estimation results under the semiparametric GLM. Appendix E studies the extension to the missing data and selection bias problem. Appendix F studies the extension to the multiple datasets inference problem. Appendix G contains the proofs of lemmas and theorems shown in this document. Appendix H considers the confidence regions and hypothesis tests for multi-dimensional parameter of interest. Finally, Appendix I contains further simulation results.

APPENDIX B: ADDITIONAL PROOFS OF MAIN RESULTS

In this appendix, we present the proofs of Corollaries 4.1, 4.2, and Theorem 4.2. For notational simplicity, denote $M := \max_{i < j} \| (y_i - y_j)(x_i - x_j) \|_\infty$.

B.1. Proof of Corollary 4.1. By Theorem 4.1, it is suffices to show $|\hat{\sigma}^2 - \sigma^2| = o_P(1)$ and $|\tilde{H}_{\alpha|\gamma} - H_{\alpha|\gamma}| = o_P(1)$. We provide the following Lemma that shows the concentration of $\hat{\Sigma}$.

**Lemma B.1.** Under the same conditions as in Corollary 4.1, it holds that

$$\| \hat{\Sigma} - \Sigma \|_\infty = O_P \left( M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}} \right).$$

**Proof.** The detailed proof is shown in Supplementary Appendix G. ∎

Given this lemma, we now prove Corollary 4.1. Recall that

$$\sigma^2 = \Sigma_{\alpha\alpha} - 2w^T \Sigma_{\gamma\alpha} + w^T \Sigma_{\gamma\gamma} w \quad \text{and} \quad \tilde{\sigma}^2 = \hat{\Sigma}_{\alpha\alpha} - 2\hat{w}^T \hat{\Sigma}_{\gamma\alpha} + \hat{w}^T \hat{\Sigma}_{\gamma\gamma} \hat{w}.$$
We now rearrange these terms and group them in the following way,
\[
|\hat{\sigma}^2 - \sigma^2| \leq |\hat{\Sigma}_{\alpha\alpha} - \Sigma_{\alpha\alpha}| - 2|\hat{\mathbf{w}}^T \hat{\Sigma}_{\gamma\alpha} - \mathbf{w}^* \Sigma_{\gamma\alpha}|
\]
(B.1)
\[+ |\hat{\mathbf{w}}^T \hat{\Sigma}_{\gamma\gamma} \hat{\mathbf{w}} - \mathbf{w}^* \Sigma_{\gamma\gamma} \mathbf{w}^*| := I_1 - 2I_2 + I_3.
\]
We first consider \(I_1\). Applying Lemma B.1, we have
\[I_1 \leq ||\hat{\Sigma} - \Sigma||_\infty = O_p \left( M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}} \right).
\]
For \(I_2\), using the triangle inequality, we have
\[I_2 \leq |(\hat{\mathbf{w}} - \mathbf{w}^*)^T (\hat{\Sigma}_{\gamma\alpha} - \Sigma_{\gamma\alpha})| + |(\hat{\mathbf{w}} - \mathbf{w}^*)^T \Sigma_{\gamma\alpha}| + |\mathbf{w}^* (\hat{\Sigma}_{\gamma\alpha} - \Sigma_{\gamma\alpha})|
\]
\[:= I_{21} + I_{22} + I_{23}.
\]
By Lemmas B.1 and A.1, we can bound \(I_{21}, I_{22}\) and \(I_{23}\) respectively as follows,
\[I_{21} \leq ||\hat{\mathbf{w}} - \mathbf{w}^*||_1 ||\hat{\Sigma}_{\gamma\alpha} - \Sigma_{\gamma\alpha}||_\infty = O_p \left( M(s + s_1) \sqrt{\frac{\log d}{n}} \cdot M^3 s \sqrt{\frac{\log d}{n}} \right),
\]
\[I_{22} \leq ||\hat{\mathbf{w}} - \mathbf{w}^*||_1 \cdot ||\Sigma_{\gamma\alpha}||_\infty = O_p \left( M \cdot (s + s_1) \cdot \sqrt{\frac{\log d}{n}} \right),
\]
\[I_{23} \leq ||\mathbf{w}^*||_1 \cdot ||\hat{\Sigma}_{\gamma\alpha} - \Sigma_{\gamma\alpha}||_\infty = O_p \left( M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}} \right).
\]
It follows that
\[I_2 = O_p \left( M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}} \right).
\]
Following the similar arguments, we can bound \(I_3\) as follows,
\[I_3 \leq |\hat{\mathbf{w}}^T (\hat{\Sigma}_{\gamma\gamma} - \Sigma_{\gamma\gamma}) \hat{\mathbf{w}}| + |\hat{\mathbf{w}}^T \Sigma_{\gamma\gamma} \hat{\mathbf{w}} - \mathbf{w}^* \Sigma_{\gamma\gamma} \mathbf{w}^*| := I_{31} + I_{32}.
\]
It holds that
\[I_{31} \leq ||\hat{\mathbf{w}}||_1^2 \cdot ||\hat{\Sigma}_{\gamma\gamma} - \Sigma_{\gamma\gamma}||_\infty = O_p \left( M^3 \cdot s_1 \cdot s \cdot \sqrt{\frac{\log d}{n}} \right).
\]
To control \(I_{32}\), we apply the following lemma.

**Lemma B.2.** Let \(\mathbf{W}\) be a symmetric \((d \times d)\)-matrix and \(\hat{\mathbf{v}}\) and \(\mathbf{v} \in \mathbb{R}^d\). Then
\[|\hat{\mathbf{v}}^T \mathbf{W} \hat{\mathbf{v}} - \mathbf{v}^T \mathbf{W} \mathbf{v}| \leq ||\mathbf{W}||_\infty \cdot ||\hat{\mathbf{v}} - \mathbf{v}||_1^2 + 2 \cdot ||\mathbf{W} \mathbf{v}||_\infty \cdot ||\hat{\mathbf{v}} - \mathbf{v}||_1.
\]
Proof of Lemma B.2. Note that
\[ |\hat{v}^T W \hat{v} - v^T W v| \leq |(\hat{v} - v)^T W (\hat{v} - v)| + 2 \cdot |v^T W (\hat{v} - v)| \]
\[ \leq \|W\|_\infty \cdot \|\hat{v} - v\|_1^2 + 2 \cdot \|Wv\|_\infty \cdot \|\hat{v} - v\|_1. \]

The proof is complete.

By Lemma B.2, we can show that
\[ I_{32} \leq \|\Sigma_{\gamma}\|_\infty \|\hat{w} - w^*\|_1^2 + \|\Sigma_{\gamma n}\|_\infty \|\hat{w} - w^*\|_1 = \mathcal{O}_P \left(M(s + s_1) \sqrt{\frac{\log d}{n}} \right). \]

It follows that
\[ I_3 = \mathcal{O}_P \left(M^3 \cdot s_1 \cdot s \cdot \sqrt{\frac{\log d}{n}} \right). \]

Combining (B.1), (B.2), (B.3) and (B.4), we obtain the convergence rate
\[ |\hat{\sigma}^2 - \sigma^2| = \mathcal{O}_P \left(M^3 \cdot s_1 \cdot s \cdot \sqrt{\frac{\log d}{n}} \right) = o_P(1). \]

Now we prove \(|\hat{H}_{\alpha|\gamma} - H_{\alpha|\gamma}| = o_P(1).\) By definition, we have
\[ |\hat{H}_{\alpha|\gamma} - H_{\alpha|\gamma}| = | - \nabla_{\alpha \alpha}^2 \ell(\hat{\beta}) + \hat{w}^T \nabla_{\alpha \gamma}^2 \ell(\hat{\beta}) - H_{\alpha \alpha} + w^*^T H_{\alpha \gamma}| \]
\[ \leq |\nabla_{\alpha \alpha}^2 \ell(\hat{\beta}) + H_{\alpha \alpha} + \|\hat{w}\|_1 \|\nabla_{\alpha \gamma}^2 \ell(\hat{\beta}) + H_{\alpha \gamma}\|_\infty \]
\[ + \|H_{\alpha \gamma}\|_\infty \|\hat{w} - w^*\|_1. \]

Applying the argument in Step 3 of the proof of Theorem 4.1, we get
\[ \|\nabla^2 \ell(\hat{\beta}) + H\|_\infty = \|\nabla^2 \ell(\hat{\beta}) - \nabla^2 \ell(\beta^*)\|_\infty + \|\nabla^2 \ell(\beta^*) + H\|_\infty \]
\[ = \mathcal{O}_P \left(M \cdot s \cdot \sqrt{\frac{\log d}{n}} + M^2 \cdot \sqrt{\frac{\log d}{n}} \right). \]

Therefore, \(|\nabla_{\alpha \alpha}^2 \ell(\hat{\beta}) + H_{\alpha \alpha} + \|\hat{w}\|_1 \|\nabla_{\alpha \gamma}^2 \ell(\hat{\beta}) + H_{\alpha \gamma}\|_\infty = \mathcal{O}_P \left(M \cdot (M + s) \cdot \sqrt{s_1 \log d/n} \right) = o_P(1).\) Moreover, \(|H_{\alpha \gamma}\|_\infty \|\hat{w} - w^*\|_1 = o_P(1).\) Hence by (B.5), we conclude that \(|\hat{H}_{\alpha|\gamma} - H_{\alpha|\gamma}| = o_P(1).\)

Applying the result of Theorem 4.1 and Slusky’s theorem, we obtain the conclusion of the corollary.
B.2. Proof of Corollary 4.2. In the previous section we proved that \(|\hat{\sigma}^2 - \sigma^2| = o_p(1)\) and \(|\hat{H}_{\alpha|\gamma} - H_{\alpha|\gamma}| = o_p(1)\). Therefore, by applying Theorem 4.2 and Slusky’s theorem, we obtain

\[(4 \cdot \hat{\sigma}^2)^{-1} \cdot \hat{H}_{\alpha|\gamma} \cdot \Lambda_n \sim \chi^2_1.\]

Thus, we have \(\lim_{n \to \infty} P(\psi_{DLRT}(\xi) = 1 \mid H_0) = \lim_{n \to \infty} P\left((4 \cdot \hat{\sigma}^2)^{-1} \cdot \hat{H}_{\alpha|\gamma} \cdot \Lambda_n > \chi^2_{1\xi}\right) = \xi.\) Similarly, for any \(t \in (0,1)\), we have

\[\lim_{n \to \infty} P(P_{DLRT} < t) = \lim_{n \to \infty} P\left(\chi^2_{1}((4 \cdot \hat{\sigma}^2)^{-1} \cdot \hat{H}_{\alpha|\gamma} \cdot \Lambda_n > 1 - t)\right) = \lim_{n \to \infty} P\left((4 \cdot \hat{\sigma}^2)^{-1} \cdot \hat{H}_{\alpha|\gamma} \cdot \Lambda_n > \chi^2_{1t}\right) = t.\]

This completes the proof.

B.3. Proof of Theorem 4.2. By the first order KKT condition, we have \(\ell_n'(\hat{\alpha}^P) = 0.\) Hence, using Taylor expansion, we have for some \(\hat{\alpha}_1\) lying between \(\alpha_0\) and \(\hat{\alpha}\) that

\[\hat{\ell}_n(\alpha_0) - \hat{\ell}_n(\hat{\alpha}^P) = \hat{\ell}_n(\hat{\alpha}^P)(\alpha_0 - \hat{\alpha}^P) + \frac{1}{2} \hat{\ell}''_n(\hat{\alpha}_1)(\hat{\alpha}^P - \alpha_0)^2 = \frac{1}{2} \hat{\ell}''_n(\hat{\alpha}_1)(\hat{\alpha}^P - \alpha_0)^2.\]

Under the null hypothesis, \(\alpha^* = \alpha_0.\) Therefore,

\[\Lambda_n = -2n\left\{\hat{\ell}_n(\alpha_0) - \hat{\ell}_n(\hat{\alpha}^P)\right\} = -\hat{\ell}''_n(\hat{\alpha}_1)\{\sqrt{n} \cdot (\hat{\alpha}^P - \alpha^*)\}^2.\]

By Theorem 4.1, we have \(\sqrt{n} \cdot (\hat{\alpha}^P - \alpha^*) \sim N(0, 4\sigma^2 \cdot H_{\alpha|\gamma}^{-2}).\) Moreover, applying the exact same argument as Step 3 in the proof of Theorem 4.1, we obtain \(-\hat{\ell}''_n(\hat{\alpha}_1) = H_{\alpha|\gamma} + o_p(1).\) Therefore, applying Slusky and continuous mapping theorem, we have

\[(4\sigma^2)^{-1} H_{\alpha|\gamma} \Lambda_n \sim \chi^2_1.\]

This completes the proof.

APPENDIX C: PROOFS OF TECHNICAL LEMMAS

In this appendix, we present the proofs of Lemma A.1, A.3 and Lemma A.5, A.6 used in the proof of Theorem 4.1. Before that, we first present another technical lemma on the Bernstein type concentration inequality for U-statistics [1] and the application of this inequality in our problems.
LEMMA C.1 (Bernstein’s inequality for $U$-statistics [1]). Given i.i.d. random variables $Z_1, \ldots, Z_n$ taking values in a measurable space $(\mathcal{S}, \mathcal{B})$ and a symmetric and measurable kernel function $h: \mathcal{S}^m \to \mathbb{R}$, we define the $U$-statistics with kernel $h$ as $U := \frac{1}{\binom{m}{k}} \sum_{i_1 < \cdots < i_m} h(Z_{i_1}, \ldots, Z_{i_m})$. Suppose that $\mathbb{E}h(Z_{i_1}, \ldots, Z_{i_m}) = 0$, $\mathbb{E}\{\mathbb{E}[h(Z_{i_1}, \ldots, Z_{i_m}) \mid Z_{i_1}]\}^2 = \sigma^2$ and $\|h\|_\infty \leq b$. There exists a constant $K(m) > 0$ depending on $m$ such that

$$\mathbb{P}(\|U\| > t) \leq 4 \exp\left\{ -nt^2/[2m^2\sigma^2 + K(m)b] \right\}, \forall t > 0.$$  

LEMMA C.2. Under the assumptions in Theorem 4.1, it holds that

$$\|\nabla_{\gamma\alpha} \ell(\beta^*) - \nabla_{\gamma\gamma} \ell(\beta^*)w^*\|_\infty = O_p\left( M\sqrt{\frac{\log d}{n}} \right).$$

PROOF. We prove this lemma by applying Lemma C.1. Let $x_i = (x_{i0}, x_{i\gamma})^T$ and $z_i = x_{i0} - x_{i\gamma}w^*$. Thus, we can rewrite the $U$-statistics as $U = \frac{1}{\binom{p}{k}} \sum_{i,j,k} h_{ij}^{(k)}$, with

$$h_{ij}^{(k)} = \frac{R_{ij}(\beta^*) \cdot (y_i - y_j)^2 \cdot (x_{ik} - x_{jk}) \cdot (z_i - z_j)}{(1 + R_{ij}(\beta^*))^2}.$$  

Noting that $\|w^*\|_2 = \|H_{\gamma\alpha}\|H_{\alpha\gamma}^T\|_2 \leq \lambda_{\min}(H)^{-1} \lambda_{\max}(H)$ is bounded by the eigenvalue assumption on $H$, $|y_i - y_j| \leq 2M$ and $x_i$ is uniformly bounded, we can show that $\|h_{ij}^{(k)}\| \leq CM^2\sqrt{s_1}$, for some constant $C$ not depending on $i, j, k$. In addition,

$$\mathbb{E}\{\mathbb{E}[h_{ij}^{(k)} \mid y_i, x_i]\}^2 \leq \mathbb{E}[h_{ij}^{(k)} h_{ij}^{(k)}] \leq 2mM^2 \cdot \mathbb{E}\left\{ \frac{R_{ij}(\beta^*) \cdot (y_i - y_j)^2 \cdot (z_i - z_j)}{(1 + R_{ij}(\beta^*))^2} \right\}$$

$$\leq 2mM^2 \cdot \lambda_{\max}(H) \cdot \|w^*\|_2 \leq C'M^2,$$

where $v^* = (1, w^T)^T$ and $C'$ is a positive constant. Applying Lemma C.1 and the union bound, we obtain

$$\mathbb{P}(\|U\|_\infty > t) \leq 4(d - 1) \exp\left\{ -nt^2/[8C'M^2 + CK(m)M^2\sqrt{s_1} \cdot t]\right\}.$$  

Note that $M\sqrt{s_1} \log d/n = o(1)$. Choosing $t = C''M\sqrt{\log d/n}$ for some sufficiently large $C''$ in the above inequality, we can easily see that the probability of $\|U\|_\infty > t$ tends to 0. This completes the proof. $\square$
C.1. **Proof of Lemma A.1.** Denote \( Q(w) = \frac{1}{2} w^T \nabla_{\gamma}^2 \ell(\beta) w - w^T \nabla_{\gamma}^2 \ell(\hat{\beta}) \).

By definition of \( \hat{w} \), \( Q(\hat{w}) - \lambda_1 \| \hat{w} \|_1 \geq Q(w^*) - \lambda_1 \| w^* \|_1 \). Denote \( \Delta = \hat{w} - w^* \).

After rearrangement of terms, we obtain
\[
-\frac{1}{2} \Delta^T \nabla_{\gamma}^2 \ell(\hat{\beta}) \Delta \leq -\Delta^T (\nabla_{\gamma}^2 \ell(\hat{\beta}) - \nabla_{\gamma}^2 \ell(\beta^*)) w^*
\]
\( + [\lambda_1 \| w^* \|_1 - \lambda_1 \| \hat{w} \|_1 ] : = I_1 + I_2. \) (C.1)

For \( I_2 \), by the triangle inequality, it is easy to see that
\[
I_2 \leq \lambda_1 \| w^*_S \|_1 - \lambda_1 \| \hat{w}_S \|_1 - \lambda_1 \| \hat{w}_S \|_1 \leq \lambda_1 \| \Delta_S \|_1 - \lambda_1 \| \Delta_S \|_1.
\]

Now, we consider \( I_1 \). We further separate \( I_1 \) into the following two terms,
\[
I_1 = -\Delta^T (\nabla_{\gamma}^2 \ell(\beta^*)) - \nabla_{\gamma}^2 \ell(\beta^*) w^* - \Delta^T \left[ (\nabla_{\gamma}^2 \ell(\hat{\beta}) - \nabla_{\gamma}^2 \ell(\beta^*)) - (\nabla_{\gamma}^2 \ell(\hat{\beta}) - \nabla_{\gamma}^2 \ell(\beta^*)) w^* \right]
\]
\( : = I_{11} + I_{12}. \)

For the first term \( I_{11} \), we have
\[
|I_{11}| \leq \| \Delta \|_1 \cdot \| (\nabla_{\gamma}^2 \ell(\beta^*) - \nabla_{\gamma}^2 \ell(\beta^*) w^*) \|_2 \leq CM \sqrt{\frac{\log d}{n}} \| \Delta \|_1,
\]
where the last step follows from Lemma C.2 and \( C \) is some positive constant.

Let \( x_i = (x_{i\alpha}, x_{i\gamma})^T \). By the Cauchy-Schwarz inequality, it can be shown that for some constants \( C', C'' > 0 \),
\[
|I_{12}| = \left| \left( \begin{array}{c} n \\ 2 \end{array} \right)^{-1} \sum_{1 \leq i<j \leq n} R_{ij}(\beta^*)(y_i - y_j)^2 \Delta^T (x_{ij\alpha} - x_{ij\gamma})(z_i - z_j)(u_{ij} - 1) \right|
\]
\[
\leq \sqrt{-\Delta^T \nabla_{\gamma}^2 \ell(\beta^*) \Delta} \cdot C'M \sqrt{\frac{\log d}{n}} \Delta_{\beta}
\]
\[
\leq C''M \sqrt{\frac{s \log d}{n}} \cdot \sqrt{-\Delta^T \nabla_{\gamma}^2 \ell(\beta^*) \Delta},
\]
where \( z_i = x_{i\alpha} - x_{i\gamma} w^* \), \( u_{ij} \) is defined in the proof of Lemma A.4 and \( \Delta_{\beta} = \hat{\beta} - \beta^* \). In addition, by Lemma A.4,
\[
| \Delta^T [\nabla_{\gamma}^2 \ell(\hat{\beta}) - \nabla_{\gamma}^2 \ell(\beta^*)] \Delta | \leq MS \sqrt{\frac{\log d}{n}} \cdot | \Delta^T \nabla_{\gamma}^2 \ell(\beta^*) \Delta |,
\]
which further implies
\[
| \Delta^T \nabla_{\gamma}^2 \ell(\beta^*) \Delta | \leq | \Delta^T \nabla_{\gamma}^2 \ell(\hat{\beta}) \Delta | \leq | \Delta^T \nabla_{\gamma}^2 \ell(\beta^*) \Delta |,
\]
given $Ms\sqrt{\log d/n} = o(1)$. Choose $\lambda_1 = 2CM\sqrt{\log d/n}$, and plug the bounds for $I_1$ and $I_2$ back into (C.1), we obtain
\[ -\frac{1}{2} \Delta_T \nabla^2 \ell(\beta^*) \Delta \leq C' M \sqrt{\frac{s \log d}{n}} \cdot \nabla \Delta_T \nabla^2 \ell(\beta^*) \Delta \]

(C.2)
\[ + 3CM \sqrt{\frac{\log d}{n}} \cdot \|\hat{\Delta}_{S_w}\|_1 - CM \sqrt{\frac{\log d}{n}} \cdot \|\hat{\Delta}_{S_{w_1}}\|_1. \]

If $[-\Delta_T \nabla^2 \ell(\beta^*) \Delta]^{1/2} > 2C'' M \sqrt{s \log d/n}$, (C.2) implies $\|\hat{\Delta}_{S_w}\|_1 \leq 3 \|\hat{\Delta}_{S_{w_1}}\|_1$.

Next, we need to verify that for $n$ large enough
\[ \inf_{\vec{v} \in \mathcal{C}} -s_1 \cdot (v^T \nabla^2 \ell(\beta^*) v) \geq c, \]

where $\mathcal{C} = \{ \vec{v} \in \mathbb{R}^{d-1} : ||\vec{v}_{S_{w_1}}||_1 \leq 3 ||\vec{v}_{S_w}||_1 \}$, $c$ is a positive constant and $S_w = \{j : w_j^p \neq 0\}$ is the support set for $\vec{w}^*$. By $\lambda_{\min}(H) \geq c > 0$, it yields
\[ -s_1 \cdot v^T \nabla^2 \ell(\beta^*) v \geq s_1 \cdot (c \cdot ||v||^2_2 - ||H_{\gamma \gamma} + \nabla^2 \ell(\beta^*) x|| \cdot ||v||^2_2) \]
\[ \geq c + O_p(s_1 \cdot M^2 \cdot \sqrt{\log d/n}) = c + O_p(1), \]

where the last step follows from the proof of Lemma A.4. Thus, we obtain
\[ \|\hat{\Delta}_{S_w}\|_1 \leq c^{1/2} \sqrt{s_1} \cdot [-\Delta_T \nabla^2 \ell(\beta^*) \Delta]^{1/2}. \]

By plugging into (C.2), we have
\[ [-\Delta_T \nabla^2 \ell(\beta^*) \Delta]^{1/2} \leq M \sqrt{(s + s_1) \log d/n}. \]

If $6\|\hat{\Delta}_{S_w}\|_1 \geq \|\hat{\Delta}_{S_{w_1}}\|_1$, by the same argument in (C.3) with a slightly different cone condition $\mathcal{C}' = \{ \vec{v} \in \mathbb{R}^{d-1} : ||\vec{v}_{S_{w_1}}||_1 \leq 3 ||\vec{v}_{S_w}||_1 \}$ then we have
\[ \|\hat{\Delta}\|_1 \leq 7 \|\hat{\Delta}_{S_w}\|_1 \leq \sqrt{s_1} \cdot [-\Delta_T \nabla^2 \ell(\beta^*) \Delta]^{1/2} \leq M(s + s_1) \sqrt{\frac{\log d}{n}}. \]

On the other hand, if $6\|\hat{\Delta}_{S_w}\|_1 \leq \|\hat{\Delta}_{S_{w_1}}\|_1$, (C.2) implies
\[ 0 \leq -\frac{1}{2} \Delta_T \nabla^2 \ell(\beta^*) \Delta \leq C'' M \sqrt{\frac{s \log d}{n}} \cdot \nabla [-\Delta_T \nabla^2 \ell(\beta^*) \Delta] \]
\[ - \frac{C}{2} M \sqrt{\frac{\log d}{n}} \cdot \|\hat{\Delta}_{S_{w_1}}\|_1. \]

Combining (C.4) and (C.5),
\[ \|\hat{\Delta}\|_1 \leq \frac{7}{6} \|\hat{\Delta}_{S_{w_1}}\|_1 \leq \sqrt{s} \cdot [-\Delta_T \nabla^2 \ell(\beta^*) \Delta]^{1/2} \leq M(s + s_1) \sqrt{\frac{\log d}{n}}. \]

Thus, in both cases, we have $\|\hat{\Delta}\|_1 \leq (s + s_1) \sqrt{\log d/n}$. This completes the proof.
C.2. Proof of Lemma A.3. By the symmetry of the kernel function, $U_n$ can be rewritten as follows,
\[ U_n = \frac{1}{k} \cdot \frac{1}{n!} \sum v_n(x_{i_1}, \ldots, x_{i_n}), \]
where the summation is over all $n!$ permutations of $\{1, \ldots, n\}$, and
\[ v_n(x_{i_1}, \ldots, x_{i_n}) = u(x_{i_1}, \ldots, x_{i_m}) + u(x_{i_{m+1}}, \ldots, x_{i_{2m}}) + \ldots + u(x_{i_{km-m+1}}, \ldots, x_{i_{km}}). \]
Note that $v_n(x_1, \ldots, x_n)$ is a sum of $k$ independent random variables. Then, for any $x \geq 0$ and $t > 0$, by the Markov inequality, we obtain that
\[ \mathbb{P}(U_n \geq x) = \mathbb{P}\left[ \exp \left\{ t \cdot \frac{1}{n!} \sum v_n(x_{i_1}, \ldots, x_{i_n}) \right\} \geq \exp(t \cdot k \cdot x) \right] \]
\[ \leq \exp(-t \cdot k \cdot x) \cdot \mathbb{E}\left[ \exp \left\{ \frac{1}{n!} \sum t \cdot v_n(x_{i_1}, \ldots, x_{i_n}) \right\} \right], \]  
(C.6)
where the summation is over all $n!$ permutations of $\{1, \ldots, n\}$. By Jensen inequality, (C.6) yields,
\[ \mathbb{P}(U_n \geq x) \leq \exp(-t \cdot k \cdot x) \cdot \mathbb{E}\left[ \frac{1}{n!} \sum \exp\{t \cdot v_n(x_{i_1}, \ldots, x_{i_n})\} \right] \]
\[ = \exp(-t \cdot k \cdot x) \cdot \frac{1}{n!} \sum_{s=1}^{k} \prod_{j=1}^{s} \mathbb{E}\left[ \exp\{t \cdot u(x_{i_{sm-m+1}}, \ldots, x_{i_{sm}})\} \right], \]
where the last equality follows by the independence of $u(x_{i_{sm-m+1}}, \ldots, x_{i_{sm}})$ for $s = 1, \ldots, k$. For notational simplicity, we write $u$ for $u(x_{i_{sm-m+1}}, \ldots, x_{i_{sm}})$.
By (A.3), for all $j \geq 1$ and $L_1 > 1$,
\[ \mathbb{E}[u^j] = \int_{0}^{\infty} \mathbb{P}(|u^j| > x) \cdot dx \leq L_1 \cdot \int_{0}^{\infty} \exp(-L_2 \cdot x^{1/j}) \cdot dx \]
\[ = \frac{L_1}{L_2} \cdot j! \leq \left( \frac{L_1}{L_2} \right)^j \cdot j!. \]  
(C.7)
Next, we apply the Taylor theorem for $\exp(t \cdot u)$. By $\mathbb{E}u = 0$, it yields,
\[ \mathbb{E}\{\exp(t \cdot u)\} = 1 + t \cdot \mathbb{E}u + \sum_{j=1}^{\infty} \frac{t^j \cdot \mathbb{E}u^j}{j!} = 1 + \sum_{j=1}^{\infty} \frac{t^j \cdot \mathbb{E}u^j}{j!}. \]
Together with (C.7), it follows that for $t \leq L_2/(2 \cdot L_1)$,
\[ \mathbb{E}\{\exp(t \cdot u)\} \leq 1 + \sum_{j=1}^{\infty} \left( \frac{t \cdot L_1}{L_2} \right)^j = 1 + \left( \frac{t \cdot L_1}{L_2} \right)^2 \cdot \sum_{j=0}^{\infty} \left( \frac{t \cdot L_1}{L_2} \right)^j \]
\[ \leq 1 + 2 \cdot \left( \frac{t \cdot L_1}{L_2} \right)^2 \leq \exp\left\{ 2 \cdot \left( \frac{t \cdot L_1}{L_2} \right)^2 \right\}. \]  
(C.8)
Combining (C.6) and (C.8), we conclude that if \( t \leq \frac{L_2}{2 \cdot L_1} \)

\[
\mathbb{P}(U_n \geq x) \leq \exp(-t \cdot k \cdot x) \cdot \exp\left( \frac{2 \cdot L_2^2 \cdot t^2}{L_2^2} \cdot k \right).
\]

Then, we can optimize the upper bound with respect to \( t \) for any given \( x \). This yields \( t = \min\{L_2^2 \cdot x/(4 \cdot L_1^2), L_2/(2 \cdot L_1)\} \). Then

\[
\mathbb{P}(U_n \geq x) \leq \exp\left( -\min\left\{ \frac{L_2^2 \cdot x^2}{8 \cdot L_1^2}, \frac{L_2 \cdot x}{4 \cdot L_1} \right\} \cdot k \right).
\]

Applying the previous argument to \(-U_n\), we obtain

\[
\mathbb{P}(U_n \leq -x) \leq \exp\left( -\min\left\{ \frac{L_2^2 \cdot x^2}{8 \cdot L_1^2}, \frac{L_2 \cdot x}{4 \cdot L_1} \right\} \cdot k \right).
\]

The result follows by a combination of these two bounds.

**C.3. Proof of Lemma A.5.**

**Proof of Lemma A.5.** By the definition of \( \mathbf{g}(y_i, x_i, \beta^*) \), we have

(C.9) \[
\hat{U}_n = \frac{2}{n(n-1)} \cdot \frac{1}{\sqrt{n-1}} \sum_{i=1}^{n} \sum_{j \neq i} h_{ij}, \quad \text{and} \quad h_{ij} = \mathbb{E}(h_{ij} | y_i, x_i),
\]

where \( h_{ij} = h_{ij}(\beta^*) \) is given by (A.4) and \( \mathbf{g}(y_i, x_i, \beta^*) = \frac{1}{n-1} \cdot \sum_{j \neq i} h_{ij} \).

Note that

\[
\frac{\sqrt{n}}{2} \cdot (\mathbf{b}^T \Sigma \mathbf{b})^{-1/2} \cdot \mathbf{b}^T \nabla \ell(\beta^*) = (\mathbf{b}^T \Sigma \mathbf{b})^{-1/2} \cdot \frac{1}{\sqrt{n}} \sum_{i=1}^{n} \mathbf{b}^T \mathbf{g}(y_i, x_i, \beta^*)
\]

\[
+ \frac{\sqrt{n}}{2} \cdot (\mathbf{b}^T \Sigma \mathbf{b})^{-1/2} \cdot \mathbf{b}^T \{\nabla \ell(\beta^*) - \hat{U}_n \} := I_1 + I_2.
\]

Note that \( \mathbb{E}\{\mathbf{g}(y_i, x_i, \beta^*)\} = \mathbb{E}(h_{ij}) = 0 \). Hence, \( \mathbf{b}^T \mathbf{g}(y_i, x_i, \beta^*) \) in \( I_1 \) are mutually independent mean-zero random variables. In addition, we have \( \text{Cov}(I_1) = 1 \). To apply the central limit theorem for \( I_1 \), we now verify the Lyapunov condition for \( I_1 \). By Assumption 4.1, \( \mathbf{b}^T \Sigma \mathbf{b} \) is lower bounded by \( \lambda_{\min} \), and

\[
n^{-3/2} \sum_{i=1}^{n} \mathbb{E}[|\mathbf{b}^T \Sigma \mathbf{b}|^{-1/2} \mathbf{b}^T \mathbf{g}(y_i, x_i, \beta^*)|^3] = O(1) \cdot n^{-3/2} \sum_{i=1}^{n} \mathbb{E}|\mathbf{b}^T \mathbf{g}(y_i, x_i, \beta^*)|^3.
\]
Let $\mathcal{B}$ denote the support set of the vector $\mathbf{b}$. Note that $\|\mathbf{b}_{\mathcal{B}}\|_2 \leq \|\mathbf{b}\|_2 = 1$ and $\mathbf{b}^T \mathbf{g}(y_i, \mathbf{x}_i, \beta^*) = \mathbf{b}_{\mathcal{B}}^T \mathbf{g}_{\mathcal{B}}(y_i, \mathbf{x}_i, \beta^*)$. By the Cauchy inequality, we have

$$n^{-3/2} \cdot \sum_{i=1}^{n} \mathbb{E}[\mathbf{b}^T \mathbf{g}(y_i, \mathbf{x}_i, \beta^*)]^3 \leq n^{-3/2} \cdot \sum_{i=1}^{n} \mathbb{E}[\|\mathbf{g}_{\mathcal{B}}(y_i, \mathbf{x}_i, \beta^*)\|^3]_2.$$  

By (A.4), it is easy to show that $\|\mathbf{h}_{ij}\|_\infty \leq M$, which implies $\|\mathbf{h}_{ij|i}\|_\infty \leq M$, and $\|\mathbf{g}(y_i, \mathbf{x}_i, \beta^*)\|_\infty \leq M$. Moreover, by assumption $|\mathcal{B}| \leq \tilde{n}$ and the Hölder inequality, we obtain

$$n^{-3/2} \cdot \sum_{i=1}^{n} \mathbb{E}[\mathbf{b}^T \mathbf{g}(y_i, \mathbf{x}_i, \beta^*)]^3 = \mathcal{O}_\mathbb{P}(\tilde{n}^{3/2} \cdot n^{-1/2} \cdot M^3) = \mathcal{O}_\mathbb{P}(1).$$

Thus, the Lyapunov Central Limit Theorem implies $I_1 \sim \mathcal{N}(0, 1)$. In the following, we shall show that $I_2 = \mathcal{O}_\mathbb{P}(1)$. Note that $I_2$ can be rewritten as

$$I_2 = \frac{\sqrt{n}}{2} \cdot \mathbb{E}[\mathbf{b}^T \mathbf{b}]^{-1/2} \cdot \frac{1}{n(n-1)} \cdot \sum_{i<j} \mathbf{b}^T \mathbf{w}_{ij},$$

where $\mathbf{w}_{ij} = \mathbf{h}_{ij} - \mathbf{h}_{ij|i} - \mathbf{h}_{ij|j}$. Next, we would like to calculate the variance of $I_2$. This requires to calculate the covariance of $\mathbf{w}_{ij}$ and $\mathbf{w}_{ik}$. To this end, we have to separately consider several situations according to the equality among $i, j, l, k$. In the first case, for $i \neq l, k$ and $j \neq l, k$,

$$\mathbb{E}(\mathbf{w}_{ij}^T \mathbf{w}_{ik}^T) = \mathbb{E}((\mathbf{h}_{ij})^T (\mathbf{h}_{ik})^T) - \mathbb{E}((\mathbf{h}_{ij}^T) (\mathbf{h}_{ik}^T)) - \mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) - \mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T)
+ \mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) + \mathbb{E}((\mathbf{h}_{ij|j})^T (\mathbf{h}_{ik|k})^T).
$$

(C.10)

For the first term, $\mathbb{E}((\mathbf{h}_{ij})^T (\mathbf{h}_{ik})^T) = \mathbb{E}((\mathbf{h}_{ij}^T) (\mathbf{h}_{ik}^T)) = \mathbf{0}$, followed by the independence of $\mathbf{h}_{ij}$ and $\mathbf{h}_{ik}$. Similarly, using the independence and the mean 0 results $\mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) = \mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) = \mathbf{0}$, all these nine terms in (C.10) are 0. This implies $\mathbb{E}(\mathbf{w}_{ij}^T \mathbf{w}_{ik}^T) = \mathbf{0}$. Similar to (C.10), if only one of $i, j$ is identical to one of $l, k$, say $i = l$, then

$$\mathbb{E}(\mathbf{w}_{ij}^T \mathbf{w}_{ik}^T) = \mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) = \mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) = \mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T),$$

where the remaining terms in (C.10) are 0 by the same arguments. Note that

$$\mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) = \mathbb{E}((\mathbf{h}_{ij|i})^T | y_i, \mathbf{x}_i) \mathbb{E}((\mathbf{h}_{ik|k})^T | y_i, \mathbf{x}_i) = \mathbb{E}((\mathbf{h}_{ij|i})^T | h_{ik|k})^T,$$

$$\mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) = \mathbb{E}((\mathbf{h}_{ij|i})^T | y_i, \mathbf{x}_i) \mathbb{E}((\mathbf{h}_{ik|k})^T | y_i, \mathbf{x}_i) = \mathbb{E}((\mathbf{h}_{ij|i})^T | h_{ik|k})^T,$$

$$\mathbb{E}((\mathbf{h}_{ij|i})^T (\mathbf{h}_{ik|k})^T) = \mathbb{E}((\mathbf{h}_{ij|i})^T | y_i, \mathbf{x}_i) \mathbb{E}((\mathbf{h}_{ik|k})^T | y_i, \mathbf{x}_i) = \mathbb{E}((\mathbf{h}_{ij|i})^T | h_{ik|k})^T.$$
Therefore, $E(w_{ij}w_{lk}^T) = 0$. Then, the nontrivial covariance of $w_{ij}$ and $w_{lk}$ must have $i = l$ and $j = k$ if $i < j, l < k$. This leads to

$$
E(I_2^2) = n \cdot (b^T \Sigma b)^{-1} \cdot \frac{1}{n^2(n-1)^2} \cdot \sum_{i<j} \sum_{l<k} b^T E(w_{ij}w_{lk}^T) b
$$

$$
= n \cdot (b^T \Sigma b)^{-1} \cdot \frac{1}{n^2(n-1)^2} \cdot \sum_{i<j} b^T E(w_{ij}w_{ij}^T) b.
$$

Let $B$ denote the support set of the vector $b$. Note that $|B| \leq \tilde{s}$ and $(b^T \Sigma b)^{-1} = O(1)$. Then

(C.11) \hspace{1cm} E(I_2^2) = O(1) \cdot \frac{1}{n(n-1)^2} \cdot \sum_{i<j} \lambda_{\max}\{E(w_{Bij}w_{Bij}^T)\}.

Since $||h_{ij}||_\infty \leq M$, $||h_{ij}||_\infty \leq M$, we obtain $||w_{ij}w_{ij}^T||_\infty = O_P(M^2)$, and therefore,

(C.12) \hspace{1cm} \lambda_{\max}\{E(w_{Bij}w_{Bij}^T)\} \leq \tilde{s} \cdot ||w_{ij}w_{ij}^T||_\infty = O_P(\tilde{s} \cdot M^2).

Combining (C.11) and (C.12), we obtain $E(I_2^2) = O_P(\tilde{s} \cdot M^2/n) = o_P(1)$. By the Markov inequality, we have $I_2 = o_P(1)$. Applying the Slutsky’s Theorem, we finish the proof.

Proof of Lemma A.6. Define the event $E_\alpha = \{||\hat{\alpha}^P - \alpha^*|| \leq C \cdot \sqrt{\log n/n}\}$ for some constant $C$. In the following we show that

$$
\lim_{n \to \infty} P(E_\alpha^c) = 0,
$$

for some constant $C$. Define the set $D := \{\alpha : ||\alpha - \alpha^*|| \leq C \cdot \sqrt{\log n/n}\}$ and let $G(\alpha) := -\hat{\ell}''(\alpha^*)^{-1}(\hat{\ell}'(\alpha^*) + \hat{\ell}'(\alpha)(\alpha - \alpha^*)) + \alpha$. If there exists $\alpha \in D$ such that $G(\alpha) = \alpha$, then we have $\hat{\ell}'(\alpha) = 0$. This implies $\alpha = \hat{\alpha}$, which further implies that $\hat{\alpha} \in D$. By Brouwer Fixed Point theorem, there exists $\alpha \in D$ such that $G(\alpha) = \alpha$ if $G(D) \subset D$. Hence, by the above chain of arguments, to show $\lim_{n \to \infty} P(E_\alpha^c) = 0$, it suffices to show that

$$
\lim_{n \to \infty} P(G(D) \subset D) = 1.
$$

For any $\alpha \in D$, by Taylor expansion, it holds for some intermediate value $\bar{\alpha}$ that

$$
G(\alpha) = -\hat{\ell}''(\alpha^*)^{-1}(\hat{\ell}'(\alpha^*) + \hat{\ell}'(\bar{\alpha})(\alpha - \alpha^*)) + \alpha
$$

$$
= -\hat{\ell}''(\alpha^*)^{-1}\left\{\hat{\ell}'(\alpha^*) + (\hat{\ell}'(\bar{\alpha}) - \hat{\ell}'(\alpha^*))((\alpha - \alpha^*)) \right\} + \alpha
$$

(C.13)
We first show that $-\hat{\ell}_n''(\alpha^*)^{-1}$ is upper bounded with high probability. Note that
\begin{align}
-\hat{\ell}_n''(\alpha^*) &= \left[ -\hat{\ell}_n''(\alpha^*) + (1, \hat{w}^T) \nabla^2 \ell(\beta^*)(1, \hat{w}^T)^T \right] \\
&- \left[ (1, \hat{w}^T) \nabla^2 \ell(\beta^*)(1, \hat{w}^T)^T + H_{\alpha|\gamma} \right] = I_1 + I_2 + H_{\alpha|\gamma}.
\end{align}
(C.14)

The analysis of (C.14) is similar to that of (A.11) with $\bar{\alpha}$ replaced by $\alpha^*$. For $I_1$, we have $\| (\alpha^*, \hat{\gamma}(\alpha^*)^T) - \beta^* \|_1 = \| \hat{\gamma} - \gamma \|_1 + |\bar{\alpha} - \alpha^*| \| w^* \|_1 = O_P \{ \max \{ s, s_1 \} \cdot \sqrt{\log d/n} \}$. Similar to (A.11), we can show that
\begin{align}
I_1 &= O_P \left( M \cdot \max \{ s, s_1 \} \cdot \sqrt{\log d/n} \right) = o_P(1).
\end{align}
Moreover, $I_2$ is the same as $I_4$ in (A.11), hence $I_2 = o_P(1)$. Therefore, we have $| \hat{\ell}_n''(\alpha^*) + H_{\alpha|\gamma} | = o_P(1)$. As $H_{\alpha|\gamma} = O(1)$, we conclude that
\begin{align}
-\hat{\ell}_n''(\alpha^*)^{-1} \text{ is upper bounded with probability tending to 1.}
\end{align}
(C.15)

Next we obtain an upper bound for $\hat{\ell}_n''(\alpha^*)$. We showed in the proof of Theorem 4.1 that $\sqrt{n} \hat{\ell}_n''(\alpha^*) = \sqrt{n} S(\beta^*) + o_P(1)$. Moreover, by the proof of Lemma A.5, we have
\begin{align}
\sqrt{n} S(\beta^*) &= \sqrt{n} (1, -w^*^T) \hat{U}_n + \sqrt{n} \{ S(\beta^*) - (1, -w^*^T) \hat{U}_n \} \\
&= I_3 + I_4.
\end{align}
(C.16)

By definition, we have $\hat{U}_n = 2n^{-1} \sum_{i=1}^n g(y_i, x_i, \beta^*)$. Moreover, $g(y_i, x_i, \beta^*)$ are i.i.d. Hence
\begin{align}
\mathbb{E} \left[ (\sqrt{n} (1, -w^*^T) \hat{U}_n)^2 \right] &= 4n^{-1} \mathbb{E} \left[ \left\{ \sum_{i=1}^n (1, -w^*^T) g(y_i, x_i, \beta^*) \right\}^2 \right] \\
&= \mathbb{E} \left[ \left\{ (1, -w^*^T) g(y_i, x_i, \beta^*) \right\}^2 \right] \leq \|(1, -w^*^T) \|^2 \cdot \lambda_{\max}(\Sigma),
\end{align}
which is bounded by a constant. Applying Markov’s inequality, we have
\begin{align}
P \left( | I_3 | \geq \sqrt{\log n} \right) &\leq \frac{\mathbb{E} \left[ (\sqrt{n} (1, -w^*^T) \hat{U}_n)^2 \right]}{\log n} = o(1).
\end{align}
This implies that $I_3 \leq \sqrt{\log n}$ with probability tending to 1. Moreover, by the proof of Lemma A.5, we have $I_4 = o_P(1)$. Therefore, by (C.16), we have
\begin{align}
\hat{\ell}_n''(\alpha^*) \leq \sqrt{\log n/n} \text{ with probability tending to 1.}
\end{align}
(C.17)
Lastly, we bound the term $(\alpha - \alpha^*)(\hat{\ell}_n''(\tilde{\alpha}) - \ell''(\alpha^*))$. By the formula for 
\( \hat{\ell}_n''(\tilde{\alpha}) - \ell''(\alpha^*) \)\), we have

\[
\hat{\ell}_n''(\tilde{\alpha}) - \ell''(\alpha^*) = (1, -\hat{\mathbf{w}}^T)\nabla^2 \ell(\tilde{\alpha}, \hat{\gamma}(\tilde{\alpha})) - \nabla^2 \ell(\alpha^*, \hat{\gamma}(\alpha^*)) (1, -\hat{\mathbf{w}}^T)^T.
\]

As \( \tilde{\alpha} \in \mathcal{D} \), we have \( \| (\tilde{\alpha}, \hat{\gamma}(\tilde{\alpha})^T) - (\alpha^*, \hat{\gamma}(\alpha^*)^T) \|_1 \leq |\tilde{\alpha} - \alpha^*|(1 + \| \hat{\mathbf{w}} \|_1) \lesssim M \cdot \sqrt{s_1 \log n/n} \). Therefore, by (C.18) and the similar argument to the proof of (A.14), we conclude that \( \sup_{\alpha \in \mathcal{D}} |\hat{\ell}_n''(\tilde{\alpha}) - \ell''(\alpha^*)| \lesssim M^2 \cdot \sqrt{s_1 \log n/n} \), which implies

\[
\sup_{\alpha \in \mathcal{D}} |(\alpha - \alpha^*)(\hat{\ell}_n''(\tilde{\alpha}) - \ell''(\alpha^*))| \lesssim M^2 \cdot s_1^{1/2} \cdot \log n/n \lesssim \sqrt{\log n/n},
\]

where we used the scaling condition that for any given \( \delta > 0 \),

\[
M^2 \cdot \sqrt{s_1 \log n/n} \lesssim s_1^{1/2}/n^{1/2 - \delta} = o(1),
\]

by (4.1). Combining (C.13), (C.15), (C.17) and (C.19), we conclude that

\[
\lim_{n \to \infty} \mathbb{P}(G(\mathcal{D}) \subset \mathcal{D}) = \lim_{n \to \infty} \mathbb{P}\left( \sup_{\alpha \in \mathcal{D}} |G(\alpha) - \alpha^*| \lesssim \sqrt{\log n/n} \right) = 1,
\]

which concludes the proof.

APPENDIX D: RESULTS FOR PARAMETER ESTIMATION

In this section, we first present the error bounds in \( \ell_q \) norm \( (q \geq 1) \) for parameter estimation with the Lasso penalty. Then we present the results with the nonconvex penalty. Finally, we present a lemma which verifies the assumed conditions hold with high probability.

D.1. Error Bounds in the \( \ell_q \) Norm for Lasso Estimator. Let \( \beta^* = (\beta_1^*, ..., \beta_d^*)^T \) denote the vector of true parameter. Consider the optimization problem (4.2) with the Lasso penalty

\[
\hat{\beta} = \arg \max_{\beta} \left\{ \ell(\beta) - \lambda \sum_{j=1}^{d} |\beta_j| \right\}.
\]

To bound the estimation error of \( \hat{\beta} \), we need to impose conditions on the minimal eigenvalues of the Hessian matrix associated with the vectors in a restricted set. In GLMs, the compatibility factor [7], restricted eigenvalue [2] and weak cone invertibility factor [9] have been commonly used to control
the estimation error for the Lasso estimator. For the proposed model, given a constant $\xi$, we similarly define the compatibility factor, restricted eigenvalue and weak cone invertibility factor as

$$
\kappa(\nabla^2 \ell(\beta^*), s) = \min \left\{ -s^{1/2} (v^T \nabla^2 \ell(\beta^*) v)^{1/2} : v \in \mathbb{R}^d \setminus \{0\}, ||v_S||_1 \leq \xi ||v||_1 \right\},
$$

$$
\text{RE}(\nabla^2 \ell(\beta^*), s) = \min \left\{ -\frac{v^T \nabla^2 \ell(\beta^*) v}{||v||_2} : v \in \mathbb{R}^d \setminus \{0\}, ||v_S||_1 \leq \xi ||v||_1 \right\},
$$

and

$$
\rho_q(\nabla^2 \ell(\beta^*), s) = \min \left\{ -s^{1/q} \frac{v^T \nabla^2 \ell(\beta^*) v}{||v||_q} : v \in \mathbb{R}^d \setminus \{0\}, ||v_S||_1 \leq \xi ||v||_1 \right\},
$$

where $S = \{ j : \beta_j^* \neq 0 \}$ denotes the support set of $\beta^*$ and $s = |S|$ is the cardinality of $S$. For notational simplicity, we suppress their dependence on the constant $\xi$. The following theorem establishes the nonasymptotic estimation error bounds.

**Theorem D.1.** Assume that the following two events

(D.1) $\mathcal{A}_1 = \left\{ \max_{1 \leq i < j \leq n} ||(y_i - y_j)(x_i - x_j)||_\infty \leq M \right\}, \quad \mathcal{A}_2 = \left\{ ||\nabla \ell(\beta^*)||_\infty \leq \frac{(\xi - 1)\lambda}{\xi + 1} \right\},$

hold for some constant $\xi > 1$ and some $M$, and $\tau = M(\xi + 1)s\lambda / 2\kappa^2(\nabla^2 \ell(\beta^*), s) < e^{-1}$. Then

(D.2) $||\hat{\beta} - \beta^*||_1 \leq \frac{\exp(\eta)(\xi + 1)}{2\kappa^2(\nabla^2 \ell(\beta^*), s)} s\lambda,$

(D.3) $||\hat{\beta} - \beta^*||_2 \leq \frac{2\exp(\eta)\xi}{(1 + \xi)\text{RE}(\nabla^2 \ell(\beta^*), s)} s^{1/2} \lambda,$

(D.4) $||\hat{\beta} - \beta^*||_q \leq \frac{2\exp(\eta)\xi}{(1 + \xi)\rho_q(\nabla^2 \ell(\beta^*), s)} s^{1/q} \lambda, \quad q \geq 1,$

(D.5) $||\hat{\beta}||_0 \leq \frac{\exp(4\eta)\phi_{\max}^2}{\text{RE}^2(\nabla^2 \ell(\beta^*), s)} s,$

where $\eta \leq 1$ is the smallest $z$ satisfying $z \exp(-z) = \tau$, and $\phi_{\max}$ is the maximum eigenvalue of $-\nabla^2 \ell(\beta^*)$. In addition,

$$
\left[ (\hat{\beta} - \beta^*)^T \nabla^2 \ell(\beta^*) (\hat{\beta} - \beta^*) \right]^{1/2} \leq \frac{2\xi \exp(\eta)}{(\xi + 1)\text{RE}^{1/2}(\nabla^2 \ell(\beta^*), s)} s^{1/2} \lambda.
$$

**Proof.** The detailed proof is shown in Supplementary Appendix G. □

imsart-aos ver. 2014/10/16 file: supp.tex date: April 17, 2017
In many applications, it is often reasonable to assume the covariates are uniformly bounded. In this case, $A_1$ holds for some constant $M$, provided $y_i$ is also uniformly bounded, which is true for the binary or categorical outcomes. On the other hand, if $y_i$ follows the sub-Gaussian or sub-exponential distribution, then $A_1$ holds with probability tending to 1, with $M = C \sqrt{\log n}$ for some sufficiently large constant $C$. In addition, Lemma A.2 implies $\| \nabla \ell(\beta^*) \|_\infty \leq C'' \cdot \sqrt{\log d/n}$ with high probability. This suggests that we can take $\lambda \approx \sqrt{\log d/n}$. In the end of this section, we shall show that the restricted eigenvalue $\text{RE}^2(\nabla^2 \ell(\beta^*), s)$ is lower bounded by a positive constant under the Gaussian, logistic and Poisson models. The same conclusions also hold for the compatibility factor and weak cone invertibility factor.

Up to a multiplicative constant, the upper bounds in (D.2), (D.3) and (D.4) are identical to those in the linear regression [2] and GLMs [7]. Indeed, [6] established the minimax lower bound in the sparse linear regression with Gaussian noise, that is $\min \lambda \max_{\beta \in B_0(s)} \| \hat{\beta} - \beta^* \|_2 \geq \sqrt{s \log(d/s)/n}$ with positive probability, where $B_0(s) = \{ \beta \in \mathbb{R}^d : \| \beta \|_0 \leq s \}$ is the $L_0$-ball with radius $s$. Since the linear regression with Gaussian noise is a parametric submodel, this also serves as a lower bound for the semiparametric GLM. Compared with (D.3), we conclude that the upper bound for $\hat{\beta}$ is identical to the lower bound up to a logarithmic factor. Therefore, $\hat{\beta}$ is nearly rate optimal in the minimax sense under the semiparametric GLM.

**D.2. Error Bounds for the Nonconvex Estimator.** In this section, we establish the statistical consistency of $\hat{\beta}$, which is the solution to the optimization problem (4.2) with a nonconvex penalty function. The theoretical results are shown in the following corollary.

**Corollary D.1.** Assume that there exist constants $\rho$, $\tau$ and $r > 0$ such that for any $v \in \mathbb{R}^d$ and $\| v \|_1 \leq r$, it satisfies

$$-v^T \nabla^2 \ell(\beta^*) v \geq \rho \cdot \| v \|_2^2 - \tau \cdot \| v \|_1^2 \cdot \frac{\log d}{n}. $$

Under the same assumptions as in Theorem D.1, we have

$$\| \hat{\beta} - \beta^* \|_2 \leq C_2 \cdot s^{1/2} \cdot \lambda, \quad \text{and} \quad \| \hat{\beta} - \beta^* \|_1 \leq C_1 \cdot s \cdot \lambda, 
$$

and $[\| \hat{\beta} - \beta^* \|_1^2 \nabla^2 \ell(\beta^*)(\hat{\beta} - \beta^*)]^{1/2} \leq C_3 \cdot s^{1/2} \cdot \lambda$, where $C_1$ and $C_2$ are two positive constants.

The proof is similar to that of Theorem D.1. We omit it for simplicity. By Lemma A.2, we have $\| \nabla \ell(\beta^*) \|_\infty \leq C'' \cdot \sqrt{\log d/n}$ with high probability.
Thus, with $\lambda = \sqrt{\log d/n}$, we obtain
\[(D.8) \quad ||\hat{\beta} - \beta^*||_2 = O_P(s^{1/2} \cdot \sqrt{\log d/n}), \quad \text{and} \quad ||\hat{\beta} - \beta^*||_1 = O_P(s \cdot \sqrt{\log d/n}),\]
and
\[(D.9) \quad [(\hat{\beta} - \beta^*)^T \nabla^2 \ell(\beta^*)(\hat{\beta} - \beta^*)]^{1/2} = O_P(s^{1/2} \cdot \sqrt{\log d/n}).\]

Note that this result justifies conditions on the initial estimator $\hat{\beta}$, and therefore the nonconvex estimator $\hat{\beta}$ can be used as an initial estimator for post-regularization inference. Since the optimization problem (4.2) is nonconvex, the obtained solution may depend on the specific algorithm for solving (4.2). [8] proposed an approximate path following algorithm, and Theorem 4.7 of [8] showed that the estimator produced by the algorithm has the same convergence rate as in (D.7), (D.8) and (D.9).

D.3. Verifying RE and RSC Conditions. Finally, we conclude this section by showing that $\text{RE}^2(\nabla^2 \ell(\beta^*), s)$ is lower bounded by a positive constant and (D.6) holds for many important GLMs, such as linear regression with Gaussian noise, logistic regression and Poisson regression, with high probability. We now justify the validity of these assumptions in the following proposition.

**Proposition D.1.** Let the mean and covariance of $x_i$ be 0 and $\Sigma_x = \text{Cov}(x_i)$ and denote $m = \max_{1 \leq i \leq n} \max_{1 \leq j \leq d} |x_{ij}|$. Assume that $x_i$ is a sub-Gaussian vector with a finite sub-Gaussian norm denoted by $C_x$, and also assume $\|\beta^*\|_2 \leq C_\beta$ for some finite constant $C_\beta$.

(a) Assume that the linear regression with Gaussian noise holds, i.e., $Y = \beta^{sT}X + \epsilon$, with $\epsilon \sim N(0, 1)$. Then, with probability at least $1 - 2 \cdot d^{-6}$,
\[(D.10) \quad -v^T \nabla^2 \ell(\beta^*)v \geq \rho \cdot \|v\|_2^2 - \tau \cdot \|v\|_1^2 \cdot \frac{\log d}{k},\]
where $\rho = C_R \cdot C_1' \cdot C_R' \cdot \lambda_{\text{min}}(\Sigma_x)$, $\tau = 4 \cdot C_\eta$ and $k = \lfloor n/2 \rfloor$. Here, $C_1'$ is an absolute positive constant, $C'_R = \exp(-2 \cdot R^2)$ and
\[(D.11) \quad C_\eta = 32 \cdot C_R \cdot m^2, \quad \text{with} \quad C_R = \frac{\exp(-4 \cdot R)}{[1 + \exp(4 \cdot R)]^2},\]
where $R$ is a constant satisfying
\[C_1'' \cdot C_x^2 \cdot \exp\left(-\frac{C''_1 \cdot R^2}{C'_\beta \cdot C_2^2}\right) \leq \lambda_{\text{min}}(\Sigma_x),\]
for some absolute positive constants $C_1^m$ and $C_1^m$. In addition, with probability at least $1 - 2 \cdot d^{-6}$,
\begin{equation}
-\mathbf{v}^T \nabla^2 \ell(\beta) \mathbf{v} \geq \rho' \| \mathbf{v} \|^2_2, \text{ where } \rho' = C_R C_R' \lambda_{\min}(\Sigma_x) - 64 C_\eta s \sqrt{\frac{|\log d|}{k}}.
\end{equation}

(b) Assume that the logistic regression for $Y$ holds, i.e., $\mathbb{P}(Y = 0 \mid \mathbf{X}) = [1 + \exp(\beta^T \mathbf{X})]^{-1}$, and $\mathbb{P}(Y = 1 \mid \mathbf{X}) = 1 - \mathbb{P}(Y = 0 \mid \mathbf{X})$. Then, with probability at least $1 - 2 \cdot d^{-6}$, (D.10) and (D.12) hold with $C'_1 = 1$, $C'_R = 2 \cdot \exp(-R) \cdot [1 + \exp(R)]^{-2}$ and $C_\eta$ is defined in (D.11).

(c) Assume that the Poisson regression, $p(y \mid \mathbf{x}) = \exp[y \cdot \beta^T \mathbf{x} - \exp(\beta^T \mathbf{x})]/y!$, holds. Then, with probability at least $1 - 2 \cdot d^{-6}$, (D.10) and (D.12) hold with $C'_1 = 1$, $C'_R = 2 \cdot \exp[-R - 2 \cdot \exp(R)]$ and $C_\eta$ is defined in (D.11).

**Proof.** The detailed proof is shown in Supplementary Appendix G.

**APPENDIX E: EXTENSIONS TO MISSING DATA**

In this section, we will illustrate how the semiparametric GLM is useful for handling high dimensional data with missing values and heterogeneity. We start from the following missing data problem.

Assume that $Y$ given $\mathbf{X}$ follows the GLMs in equation (1.1) and the missing data process is decomposable. As shown in equation (2.3), $Y$ given $\mathbf{X}$ and $\delta = 1$ satisfies the semiparametric GLM with the same finite dimensional parameter $\beta$ and unknown function $f^m(\cdot)$. Following the same regularized statistical chromatography arguments in Section 3, the conditional probability of $R_{ij}^L = r_{ij}^L$ given the order statistic $Y_{(i,j)}^L = (\min(Y_i, Y_j), \max(Y_i, Y_j))$, the covariate $(\mathbf{x}_i, \mathbf{x}_j)$ and the selection indicator $\delta_i = \delta_j = 1$ is

$$
\mathbb{P}(R_{ij}^L = r_{ij}^L \mid y_{(i,j)}^L, \mathbf{x}_i, \mathbf{x}_j, \delta_i = \delta_j = 1; \beta) = \{1 + R_{ij}(\beta)\}^{-1},
$$

where $R_{ij}(\beta)$ is given by (3.4). Thus, the composite log-likelihood function becomes

$$
\ell^m(\beta) = -\left(\begin{array}{c} n \end{array}\right)^{-1} \sum_{1 \leq i < j \leq n} \delta_i \cdot \delta_j \cdot \log \left(1 + R_{ij}(\beta)\right).
$$

Note that the samples $i$ and $j$ contribute to the loss function if and only if they are both completely observed, i.e., $\delta_i = \delta_j = 1$. Hence, $\ell^m(\beta)$ is expressed in terms of the observed data and is computable in practice. The
initial estimator is given by

\[(E.1) \quad \hat{\beta}_m \in \arg\max_{\beta} \ell^m(\beta) - \sum_{j=1}^{d} p_{\lambda_m}(\beta_j),\]

where \(\lambda_m \geq 0\) is a tuning parameter and \(p_{\lambda}(\cdot)\) is a generic penalty function (which could be nonconvex). Further discussions on the parameter estimation in the presence of missing data can be found in Supplementary Materials. In the following, we apply the main results in Section 4 to establish the limiting distribution of the maximum directional likelihood estimator and directional likelihood ratio test statistic under the null hypothesis \(H_0 : \alpha^* = 0\).

Let \(\hat{\beta}_m = (\hat{\alpha}_m, \hat{\gamma}_m)\). Consider the following directional likelihood function

\[\hat{\ell}_m(\alpha) = \ell^m(\alpha, \gamma_m + (\hat{\alpha}_m - \alpha)\hat{\omega}_m),\]

where \(\hat{\omega}_m = \arg\max \left\{ \frac{1}{2} w^T \nabla^2_{\gamma\gamma} \ell^m(\hat{\beta}_m) w - w^T \nabla^2_{\gamma\alpha} \ell^m(\hat{\beta}_m) - \lambda_m \|w\|^2 \right\} \).

Let \(\alpha_m^* = \arg\max_{\alpha \in \mathbb{R}} \hat{\ell}_m(\alpha)\), and \(\Lambda_m^* = 2n\{\hat{\ell}_m(\alpha_m^*) - \hat{\ell}_m(\alpha_0)\}\). We now establish the asymptotic properties of \(\alpha_m^* - \alpha^*\) and \(\Lambda_m^*\) under the null hypothesis \(H_0 : \alpha^* = 0\). Let \(\mathbf{H}_m = -\mathbb{E}(\nabla^2 \ell^m(\beta^*))\) and \(\mathbf{g}_m(y_i, x_i, \beta) = \frac{2}{n} \cdot \mathbb{E}(\nabla \ell^m(\beta) \mid y_i, x_i, \delta_i = 1)\). Define

\[(H_m)_{\alpha\gamma} = (H_m)_{\alpha\alpha} - (H_m)_{\alpha\gamma}[(H_m)_{\gamma\gamma}]^{-1}(H_m)_{\gamma\alpha}\]

and \(\Sigma_m = \mathbb{E}\{\mathbf{g}_m^{\otimes 2}(y_i, x_i, \beta^*)\}\).

The following assumption, analogous to Assumption 4.1, is adopted for the missing data setting, and we refer to Section 4 for more detailed discussions.

**Assumption E.1.** Assume that \(Y\) is sub-exponential which satisfies Definition 1.1, and \(|X|_{\infty} \leq m\) for a positive constant \(m\). Assume that \(c \leq \lambda_{\min}(\Sigma_m) \leq \lambda_{\max}(\Sigma_m) \leq c',\) and \(c \leq \lambda_{\min}(\mathbf{H}_m) \leq \lambda_{\max}(\mathbf{H}_m) \leq c',\) for some constants \(c, c' > 0\).

Let \(w_m^* = [(H_m)_{\gamma\gamma}]^{-1}(H_m)_{\gamma\alpha}\) and \(s_1 = ||w_m^*||_0\). The following hypothesis testing result is a direct corollary of Theorems 4.1 and 4.2. For simplicity, we omit the proof.

**Corollary E.1.** Assume that \(Y\) follows from the generalized linear model (1.1) and the missing data process satisfies Definition 2.3. Suppose Assumptions E.1 holds. Assume \(\|\hat{\Delta}\|_2 = \mathcal{O}_p(\sqrt{s \log d/n}), \|\hat{\Delta}\|_1 = \mathcal{O}_p(s \sqrt{\log d/n}),\) and \(\hat{\Delta}^T \nabla^2 \ell(\beta^*) \hat{\Delta} = \mathcal{O}_p(s \log d/n),\) where \(\hat{\Delta} = \hat{\beta}_m - \beta^*\) and \(s = \|\beta^*\|_0\). Given any small constant \(\delta > 0\), it holds that

\[
\lim_{n \to \infty} \max\{s, s_1\}^2 \cdot \log d \cdot n^{1/2 - \delta} = 0.
\]
Then with \( \lambda_m = \log n \cdot \sqrt{\log d/n} \), we have

\[
n^{1/2} \cdot (\hat{\alpha}^p - \alpha^*) \rightsquigarrow N(0, 4\sigma_m^2 \cdot (H_m)_{\alpha|\gamma}^{-2}),
\]

where \( \sigma_m^2 = (\Sigma_m)_{\alpha\alpha} - 2\mathbf{w}_m^T (\Sigma_m)_{\gamma\alpha} + \mathbf{w}_m^T (\Sigma_m)_{\gamma\gamma} \mathbf{w}_m^T \). Moreover, under the null hypothesis, it holds that \( (4 \cdot \sigma_m^2)^{-1} \cdot (H_m)_{\alpha|\gamma} \cdot \Lambda_n \rightsquigarrow \chi_1^2 \), where

\[
\hat{\sigma}_m^2 := (\hat{\Sigma}_m)_{\alpha\alpha} - 2\hat{\mathbf{w}}_m^T (\hat{\Sigma}_m)_{\gamma\alpha} + \hat{\mathbf{w}}_m^T (\hat{\Sigma}_m)_{\gamma\gamma} \hat{\mathbf{w}}_m,
\]

\[
\hat{\Sigma}_m := \frac{1}{n} \cdot \sum_{i=1}^n \left\{ \frac{1}{n-1} \cdot \sum_{j=1, j \neq i}^n \frac{\delta_i \cdot \delta_j \cdot R_{ij}(\hat{\beta}_m) \cdot (y_i - y_j) \cdot (\mathbf{x}_i - \mathbf{x}_j)}{1 + R_{ij}(\hat{\beta}_m)} \right\} \odot^2,
\]

and \( (\hat{H}_m)_{\alpha|\gamma} := -\nabla_{\alpha\alpha} \ell^m(\hat{\beta}_m) + \hat{\mathbf{w}}_m^T \nabla\gamma \ell^m(\hat{\beta}_m) \).

Similar to the previous section, the following two Lemmas are sufficient to imply the validity of the error bounds with either Lasso or nonconvex penalty function. The proof of Corollary E.1 is similar to that of Theorem 4.1 and Theorem 4.2, and we omit the proof.

In the first Lemma, it shows that \( ||\nabla \ell^m(\beta^*)||_\infty \leq C'' \cdot \sqrt{\log d/n} \) with high probability. In the second Lemma, it shows that the inequality (D.6) for \( \ell^m(\beta^*) \) holds with high probability. These two Lemmas yield that the estimator \( \hat{\beta}_m \) has the desired convergence rates with missing data and selection bias.

**Lemma E.1.** Assume that assumption E.1 holds. Then, for any \( C'' > 0 \), we have \( ||\nabla \ell^m(\beta^*)||_\infty \leq C'' \cdot \sqrt{\frac{\log d}{n}} \), with probability at least

\[
(\text{E.3}) \quad 1 - 2 \cdot d \cdot \exp \left[ -\min \left\{ \frac{C^2 \cdot C''}{29} \cdot \frac{\log d}{n}, \frac{C \cdot C''}{25} \cdot \frac{\log d}{n} \right\} \cdot k \right],
\]

where \( k = \lfloor n/2 \rfloor \), \( m = \max_{1 \leq i \leq n} \max_{1 \leq j \leq d} |x_{ij}| \), and \( C, C' \) are defined in Definition 1.1.

**Proof.** The proof is similar to Lemma A.2 and is omitted.

**Lemma E.2.** Let the mean and covariance of \( \mathbf{x}_i \) be 0 and \( \Sigma_x = \text{Cov}(\mathbf{x}_i) \) and denote \( m = \max_{1 \leq i \leq n} \max_{1 \leq j \leq d} |x_{ij}| \). Assume that \( \mathbf{x}_i \) is a sub-Gaussian vector with the finite sub-Gaussian norm denoted by \( C_x \), and also assume \( \|\beta^*\|_2 \leq C_\beta \) for some finite constant \( C_\beta \).
(a) Assume that the linear regression with Gaussian noise holds, i.e., \( Y = \beta^*^T \mathbf{X} + \epsilon \), with \( \epsilon \sim N(0, 1) \). Assume that there exists an interval \( I \supseteq [-1, 1] \) such that for any \( y \in I \) satisfies \( g_1(y) > c \) for some constant \( c > 0 \) and \( g_2(\mathbf{x}) \) is a positive constant, where \( g_1 \) and \( g_2 \) are given in definition 2.3. Then, with probability at least \( 1 - 2d^{-6} \),

\[
(E.4) \quad - \mathbf{v}^T \nabla^2 \ell_n(\beta^*) \mathbf{v} \geq \rho \cdot \| \mathbf{v} \|_2^2 - \tau \cdot \| \mathbf{v} \|_1^2 \cdot \frac{\log d}{k},
\]

where \( \rho = C_R \cdot C'_1 \cdot C''_R \cdot \lambda_{\min}(\Sigma_x) \), \( \tau = 4 \cdot C_\eta \) and \( k = \lfloor n/2 \rfloor \). Here, \( C'_1 \) is an absolute positive constant, \( C''_R = \exp(-2 \cdot R^2) \) and

\[
(E.5) \quad C_\eta = 32 \cdot C_R \cdot m^2, \quad \text{with} \quad C_R = \frac{\exp(-4 \cdot R)}{[1 + \exp(4 \cdot R)]^2},
\]

where \( R \) is a constant satisfying

\[
C''_1 \cdot C_x^2 \cdot \exp \left( - \frac{C''_1 \cdot R^2}{C'_3 \cdot C''_2} \right) \leq \lambda_{\min}(\Sigma_x).
\]

for some absolute positive constants \( C''_1 \) and \( C'_1 \).

(b) Assume that the logistic regression for \( Y \) holds, i.e., \( \mathbb{P}(Y = 0 \mid \mathbf{X}) = [1 + \exp(\beta^*^T \mathbf{X})]^{-1}, \) and \( \mathbb{P}(Y = 1 \mid \mathbf{X}) = 1 - \mathbb{P}(Y = 0 \mid \mathbf{X}) \). Assume that \( g_1(0) > c \) and \( g_1(1) > c \) for some constant \( c > 0 \). Then, with probability at least \( 1 - 2d^{-6} \), (E.4) holds with \( C'_1 = 1 \), \( C''_R = 2 \cdot c^2 \cdot \exp(-R) \cdot [1 + \exp(R)]^{-2} \), and \( C_\eta \) is defined in (E.5).

(c) Consider the Poisson regression, \( p(y \mid \mathbf{x}) = \exp[y \beta^*^T \mathbf{x} - \exp(\beta^*^T \mathbf{x})]/y! \). Assume that there exists two positive integers \( z_1 \) and \( z_2 \), \( z_1 \neq z_2 \) satisfying \( g_1(z_1) > c \) and \( g_1(z_2) > c \) for some constant \( c > 0 \). Then, with probability at least \( 1 - 2d^{-6} \), (E.4) holds with \( C'_1 = 1 \),

\[
C'_R = c^2 \cdot (z_1 - z_2)^2 \cdot \frac{1}{z_1!z_2!} \cdot \exp \left\{ - z_1 \cdot R - z_2 \cdot R - 2 \cdot \exp(R) \right\}, \quad \text{and}
\]

\[
C_\eta = 32 \cdot C_R \cdot m^2 \cdot [\max\{z_1, z_2\}]^2, \quad \text{with} \quad C_R = \frac{\exp(-4R \max\{z_1, z_2\})}{[1 + \exp(4R \max\{z_1, z_2\})]^2}.
\]

PROOF. The proof is similar to Lemma D.1 and is omitted. \( \square \)

APPENDIX F: EXTENSION TO MULTIPLE DATASETS INFECTION WITH HETEROGENEITY

Consider the following problem setup. Assume that there exist \( n_t \) samples in the \( t \)th task, where \( t = 1, ..., T \). Given \( t \), for any \( i = 1, ..., n_t \), the data
(y_{i(t)}, x_{i(t)}) are independent, and y_{i(t)} given x_{i(t)} follows the semiparametric GLM in equation (1.2). Here, we allow the sample sizes \( n_1, \ldots, n_T \) to be different, and denote \( n = \min\{n_1, \ldots, n_T\} \). In this section, we mainly focus on the finite sample estimation error bounds for this multitask learning problem.

Assume that the sparsity patterns of the \( d \)-dimensional parameter \( \beta^*_t \) are identical for any \( t = 1, \ldots, T \). In other words, the response variables depend on the same covariates across different tasks. Hence, the group Lasso penalty can be used to encourage the group sparsity. Following the statistical chromatography in Section 3, for notational simplicity we directly study the following loss function instead of the loglikelihood function for the \( t \)th task

\[
\ell_t(\beta_t) = \left( \frac{n_t}{2} \right)^{-1} \sum_{1 \leq i < j \leq n_t} \log \left( 1 + R_{tij}(\beta_t) \right),
\]

where \( R_{tij}(\beta) = \exp\{- (y_{i(t)} - y_{j(t)}) \beta_t^T (x_{i(t)} - x_{j(t)})\} \). Combining the loss functions for all tasks and applying the group Lasso penalty, we can estimate \( \beta^* = (\beta^*_1, \ldots, \beta^*_T)^T \) by

\[
\hat{\beta}_H = \arg \min_{\beta} \left\{ \ell_H(\beta) + \lambda_H \sum_{j=1}^d \left( \sum_{t=1}^T \beta_{tj}^2 \right)^{1/2} \right\},
\]

where \( \ell_H(\beta) = \sum_{t=1}^T \ell_t(\beta_t) \) is a composite loss function and \( \lambda_H > 0 \) is a tuning parameter. Note that the group Lasso penalty uses the \( L_2 \) norm to combine parameters within the group and the \( L_1 \) norm for parameters between groups. This type of penalty function can shrink all parameters within a group to 0, and therefore encourages group sparsity.

Let \( \beta^j = (\beta_{1j}, \ldots, \beta_{Tj})^T \) denote the coefficients corresponding to the \( j \)th covariate across different tasks, and \( \hat{\beta}_H^j \) denote the corresponding components in \( \hat{\beta}_H \). For every \( 1 \leq q < \infty \), we define the mixed \((2, q)\)-norm of \( \beta \) as

\[
\|\beta\|_{2,q} = \left( \sum_{j=1}^d \left( \sum_{t=1}^T \beta_{tj}^2 \right)^{q/2} \right)^{1/q} = \left( \sum_{j=1}^d \|\beta^j\|_2^q \right)^{1/q},
\]

and the \((2, \infty)\)-norm of \( \beta \) as \( \|\beta\|_{2,\infty} = \max_{1 \leq j \leq d} \|\beta^j\|_2 \). In this section, we use \( \nabla_j f(\beta) \) to denote the derivative of \( f(\beta) \) with respect to the vector \( \beta^j \) and \( \nabla_{jk}^2 f(\beta) \) to denote the mixed derivative of \( f(\beta) \) with respect to the vector \( \beta^j \) and \( \beta^k \). Following the Karush-Kuhn-Tucker (KKT) conditions,
\( \hat{\beta}_H \) is a solution to (F.2) if and only if

\[
\begin{align*}
\nabla_j \ell_H(\hat{\beta}_H) &= -\lambda_H \hat{\beta}_H^j, & \text{if } ||\hat{\beta}_H||_2 \neq 0, \\
||\nabla_j \ell_H(\hat{\beta}_H)||_2 &= \lambda_H, & \text{if } ||\hat{\beta}_H||_2 = 0.
\end{align*}
\]

Similarly, if \( \hat{\beta}_H \) is not unique, we allow \( \hat{\beta}_H \) to be any solution of equation (F.3).

**F.1. Upper Bounds for Parameter Estimation.** Let \( S_H = \{ j : \beta^{*j} \neq 0, j = 1, \ldots, d \} \) denote the group support set for \( \beta^* \), and \( s_H = |S_H| \) denote the cardinality of \( S_H \). Given the constant \( \xi \), we can generalize the compatibility factor, the restricted eigenvalue, and the weak cone invertibility factor to the multitask learning problem,

\[
\kappa_H(\nabla^2 \ell_H(\beta^*), s_H) = \min \left\{ \frac{s_H^{1/2} (v^T \nabla^2 \ell_H(\beta^*) v)^{1/2}}{||v^S_H||_2,1} : v \in \mathbb{R}^{d \times T} \setminus \{0\}, ||v^S_H||_2,1 \leq \xi ||v^H||_2,1 \right\},
\]

\[
\text{RE}_H(\nabla^2 \ell_H(\beta^*), s_H) = \min \left\{ \frac{v^T \nabla^2 \ell_H(\beta^*) v}{||v||_2,2} : v \in \mathbb{R}^{d \times T} \setminus \{0\}, ||v^S_H||_2,1 \leq \xi ||v^S_H||_2,1 \right\},
\]

\[
\rho_{Hq}(\nabla^2 \ell_H(\beta^*), s_H) = \min \left\{ \frac{s_H^{1/q} v^T \nabla^2 \ell_H(\beta^*) v}{||v^S_H||_2,1 ||v||_2,q} : v \in \mathbb{R}^{d \times T} \setminus \{0\}, ||v^S_H||_2,1 \leq \xi ||v^S_H||_2,1 \right\}.
\]

Similar to the analysis of \( L_1 \)-regularized estimator, the cone \( ||v^S_H||_2,1 \leq \xi ||v^S_H||_2,1 \) indexed by the true support set \( S_H \) is used to restrict the space for eigenvectors. In contrast, the restricted eigenvalue condition defined for the multitask linear regression in [5] is taking infimum over all possible cones \( ||v^H||_2,1 \leq \xi ||v^H||_2,1 \), where \( |J| \leq s_H \). Hence, our condition is slightly weaker than [5].

**Theorem F.1.** Assume that the two events

\[
\mathcal{A}_1 H = \left\{ \max_i \max_{i<j} ||(y_{i(t)} - y_{j(t)})(x_{i(t)} - x_{j(t)})||_\infty \leq M \right\},
\]

\[
\mathcal{A}_2 H = \left\{ ||\nabla \ell_H(\beta^*)||_2,\infty \leq \frac{(\xi - 1)\lambda_H}{\xi + 1} \right\},
\]

hold for some constant \( \xi > 1 \), and \( \tau = M(\xi + 1)s_H \lambda_H / (2\kappa^2_H(\nabla^2 \ell_H(\beta^*), s_H)) \leq \)
\[ 1/e. \] Then

\begin{align*}
\text{(F.5)} & \quad \|\hat{\beta}_H - \beta^*\|_{2,1} \leq \frac{\exp(\eta)(\xi + 1)}{2\kappa_H^2(\nabla^2 \ell_H(\beta^*), s_H)^{1/2}} s_H \lambda_H, \\
\text{(F.6)} & \quad \|\hat{\beta}_H - \beta^*\|_{2,2} \leq \frac{2\exp(\eta)\xi}{(1 + \xi) R E_H(\nabla^2 \ell_H(\beta^*), s_H)} \lambda_H, \\
\text{(F.7)} & \quad \|\beta - \beta^*\|_{2,q} \leq \frac{2\exp(\eta)\xi}{(1 + \xi) R E_H(\nabla^2 \ell_H(\beta^*), s_H)}^{1/2} s_H^{1/2} \lambda_H, \quad q \geq 1, \\
\text{(F.8)} & \quad |\{j : \hat{\beta}_H^j \neq 0\}| \leq \frac{\exp(4\eta)\xi^2 \phi_{\text{max}}^2}{R E_H^2(\nabla^2 \ell_H(\beta^*), s_H)} s_H,
\end{align*}

where \( \eta \leq 1 \) is the smallest \( z \) satisfying \( z \exp(-z) = \tau \), and \( \phi_{\text{max}} \) is the maximum eigenvalue of \( \nabla^2 \ell_H(\beta^*) \).

**Proof.** The detailed proof is shown in Supplementary Appendix G. \( \Box \)

Note that the rate of convergence in Theorem F.1 depends crucially on the choice of \( \lambda_H \). The following lemma provides the lower bound for \( \lambda_H \) in the multitask learning problem.

**Lemma F.1.** Under Assumption 4.1 and assume that \( [n/2]^{-1} \log(12d) \leq 1/2 \) holds. For \( n \geq 4 \), with probability at least \( 1 - 2\sqrt{2}(\log(12d))/(\log(2d))^{1+2\delta} \) for some \( \delta > 0 \),

\[ \|\nabla \ell_H(\beta^*)\|_{2,\infty} \leq \frac{4\sqrt{10}m\tilde{C}^{1/2}T^{1/2}}{n^{1/2}} + \frac{T^{1/4}(\log(2d))^{3/4+\delta} 32\sqrt{2}C'm}{n^{1/2}}, \]

where \( \tilde{C} = 2 \int_0^{\infty} C' \exp(-C x^{1/2}) \, dx \) and \( C, C' \) are specified in Definition 1.1. Moreover, provided

\[ \lambda_H \gtrsim \frac{T^{1/2} + T^{1/4}(\log d)^{3/4+\delta}}{n^{1/2}}, \]

with probability at least \( 1 - 2\sqrt{2}(\log(12d))/(\log(2d))^{1+2\delta} \), the event \( A_{2H} \) in (F.4) holds.

**Proof.** The detailed proof is shown in Supplementary Appendix G. \( \Box \)

**Remark 1.** Theorem F.1, Lemma F.1, together with Lemma G.6, imply that

\[ \frac{1}{\sqrt{T}} \|\hat{\beta}_H - \beta^*\|_{2,q} = O_P\left( \frac{s_H^{1/q}}{n^{1/2}} \left( 1 + \left( \frac{\log d}{T^{1/4}} \right)^{3/4+\delta} \right) \right). \]
for any $q \geq 1$, provided $n = n_1 = \cdots = n_T$. Note that we divide the estimation error by $\sqrt{T}$ such that the results can be interpreted as the error per task. Similar to [5], we find that our estimator enjoys the dimension independence phenomenon. That is, if $\frac{\log d^{3/4 + \delta}}{T^{1/4}} = o(1)$, then $\frac{1}{\sqrt{T}} \norm{\hat{\beta}_H - \beta^*}_{2,q} = \mathcal{O}_P\left(\frac{1}{n^{1/2}}\right)$, which is independent of the dimensionality $d$.

**Remark 2.** Recall that by Theorem F.1, replacing the Group Lasso penalty with the Lasso penalty, we obtain $\frac{1}{\sqrt{T}} \norm{\hat{\beta}_H - \beta^*}_{2,2} = \mathcal{O}_P\left(\sqrt{\frac{\log d}{n}}\right)$. Compared with (F.9), the Group Lasso yields faster convergence rate than the Lasso estimator, if $\frac{\log d^{3/4 + \delta}}{T^{1/4}} = o(1)$. Similar phenomenon is observed by [5] for the linear regression. Moreover, our results (F.9) with $q = 1$ are sharper than the convergence rate $\frac{1}{\sqrt{T}} \norm{\hat{\beta}_H - \beta^*}_{2,1} = \mathcal{O}_P\left(\sqrt{\frac{\log d}{n}}\right)$ obtained by [4, 3] for classical GLMs.

In order to prove Lemma F.1, we establish a new maximal moment inequality for U-statistics with unbounded kernels. This result is also of interest in its own right.

**Lemma F.2.** Let $X_1, \ldots, X_n$ be independent random variables. Consider the following $d$-dimensional U-statistics of order $m$

$$U = \sum_{i_1 < \ldots < i_m} u(X_{i_1}, \ldots, X_{i_m})/\binom{n}{m},$$

where the summation is over all $i_1 < \ldots < i_m$ selected from $\{1, \ldots, n\}$, and $\mathbb{E}\{u(X_{i_1}, \ldots, X_{i_m})\} = 0$ for all $i_1 < \ldots < i_m$. For $1 \leq j \leq d$, let $u_j(X_{i_1}, \ldots, X_{i_m})$ denote the $j$th component of $u(X_{i_1}, \ldots, X_{i_m})$. For any $M \geq 1$, define $c_M = \{c > 0 : \exp(M - 1) - 1 \leq (c - 2)d\}$ and $k = \lfloor n/m \rfloor$ to be the largest integer less than $n/m$. Assume that $k^{-1} \log(c_M d) \leq 1/2$. If there exist constants $L_1$ and $L_2$, such that for any $1 \leq j \leq d$,

$$\mathbb{P}(|u_j(X_{i_1}, \ldots, X_{i_m})| \geq x) \leq L_1 \exp(-L_2 x),$$

for all $i_1 < \ldots < i_m$ and all $x \geq 0$, then for any $M \geq 1$

$$\mathbb{E}\left(\max_{1 \leq j \leq d} |U_j|^M\right) \leq 2^{3M/2} \left(\frac{L_1}{L_2}\right)^M \left(\frac{\log(c_M d)}{k}\right)^{M/2}.$$

**Proof.** The detailed proof is shown in Supplementary Appendix G. □
F.2. Hypothesis tests. Assume that the parameter in the \( t \)th task can be partitioned into \( \beta_t = (\alpha_t, \gamma_t) \), where \( \alpha_t \) is the parameter of interest and \( \gamma_t \) is the nuisance parameter. Assume that we are interested in testing \( H_0 : \alpha_t = 0 \). Since the data from different tasks are independent, to make inference on \( \alpha_t \), we can only consider the data from the \( t \)th task. Hence, following the similar approach, the directional likelihood can be constructed based on modifying \( \ell_t(\beta_t) \) in (F.1). Hence, the inferential properties in this setting are similar to the those in the main paper. To save space, we do not replicate the details.

APPENDIX G: PROOFS OF AUXILIARY LEMMAS

In this appendix, we present the proofs of the auxiliary Lemmas in previous appendices.

G.1. Proof of Lemma B.1. We first introduce the following intermediate estimator,

\[
\hat{\Sigma}(\beta) = \frac{1}{n(n-1)^2} \sum_{i=1}^{n} \sum_{j \neq i, k \neq i} r_{ijk}(\beta),
\]

where the kernel function \( r_{ijk}(\beta) \) is defined as

\[
r_{ijk}(\beta) = \frac{R_{ij}(\beta) \cdot R_{ik}(\beta) \cdot (y_i - y_j) \cdot (y_i - y_k) \cdot (x_i - x_j) \cdot (x_i - x_k)^T}{(1 + R_{ij}(\beta)) \cdot (1 + R_{ik}(\beta))}.
\]

We have \( \hat{\Sigma} = \hat{\Sigma}(\hat{\beta}) \) and the following decomposition,

\[
\hat{\Sigma}(\hat{\beta}) - \Sigma = \{ \hat{\Sigma}(\hat{\beta}) - \hat{\Sigma}(\beta^*) \} + \{ \hat{\Sigma}(\beta^*) - \Sigma \} := I_1 + I_2.
\]

To control \( I_1 \), we will bound the derivative of \( \hat{\Sigma}(\beta) \) with respect to \( \beta \). In particular, for any \((a, b)\) element of \( r_{ijk}(\beta) \) and any \( 1 \leq l \leq d \), after some simple algebra, we can show that

\[
\left| \frac{\partial [r_{ijk}(\beta)](a,b)}{\partial \beta_l} \right| \leq M^2 \cdot \left| \frac{\partial [R_{ij}(\beta)R_{ik}(\beta)]}{\partial \beta_l} \frac{R_{ij}(\beta)R_{ik}(\beta)}{(1 + R_{ij}(\beta))(1 + R_{ik}(\beta))} \right| \\
\leq M^3 \cdot R_{ij}(\beta)R_{ik}(\beta)(1 + R_{ij}(\beta)) + R_{ij}(\beta)R_{ik}(\beta)(1 + R_{ik}(\beta)) \leq 2M^3,
\]

where \( M := \max_{1 \leq i < j \leq n} ||(y_i - y_j) \cdot (x_i - x_j)||_\infty \). Thus, by the mean value theorem and the assumption \( \| \beta - \beta^* \|_1 = O_P(s \sqrt{\log d/n}) \), we can show that

\[
[r_{ijk}(\hat{\beta}) - r_{ijk}(\beta^*)](a,b) = \frac{\partial [r_{ijk}(\beta)](a,b)}{\partial \beta} (\hat{\beta} - \beta^*) \\
\leq \left\| \frac{\partial [r_{ijk}(\beta)](a,b)}{\partial \beta} \right\| _\infty \cdot ||\hat{\beta} - \beta^*||_1 = O_P\left(M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}}\right).
\]
where $\beta$ lies in between $\hat{\beta}$ and $\beta^*$. Thus, this implies

\[(G.1) \quad ||I_1||_{\infty} = O_p\left(M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}}\right).\]

By the definition of $\Sigma$ and $h_{ij\cdot}$ in (C.9), we have

\[
\Sigma = \frac{1}{n(n-1)^2} \sum_{i=1}^{n} \sum_{j \neq i, k \neq i, k \neq j} E(h_{ij\cdot}h_{ik\cdot}^T) + \frac{1}{n(n-1)^2} \sum_{i=1}^{n} \sum_{j \neq i} E(h_{ij\cdot}^2)
\]

\[
= \frac{1}{n(n-1)^2} \sum_{i=1}^{n} \sum_{j \neq i, k \neq i, k \neq j} E(h_{ij\cdot}h_{ik\cdot}^T) + \frac{1}{n(n-1)^2} \sum_{i=1}^{n} \sum_{j \neq i} E(h_{ij\cdot}^2),
\]

where the last step follows from the fact that $h_{ij\cdot}$ and $h_{ik\cdot}$ are independent given $y_i, x_i$. Since $r_{ijk}(\beta^\star) = h_{ij\cdot}h_{ik\cdot}^T$, we have

\[
I_2 = \frac{n-2}{n-1} \left\{ \frac{1}{n(n-1)(n-2)} \sum_{j \neq i, k \neq i, j \neq k} \left[ r_{ijk}(\beta^\star) - E\{r_{ijk}(\beta^\star)\} \right] \right\}
\]

\[
+ \frac{1}{n-1} \left\{ \frac{1}{n(n-1)} \sum_{j \neq i} \left[ r_{ijj}(\beta^\star) - E\{r_{ijj}(\beta^\star)\} \right] \right\}
\]

\[
+ \frac{1}{n-1} \left\{ \frac{1}{n(n-1)} \sum_{j \neq i} \left[ E\{h_{ij\cdot}^2\} - E\{h_{ij\cdot}^2\} \right] \right\}
\]

\[
:= \frac{n-2}{n-1} I_{21} + \frac{1}{n-1} I_{22} + \frac{1}{n-1} I_{23}
\]

It is seen that $I_{21}$ is a mean-zero third order U-statistic. Note that $r_{ijk}(\beta^\star)$ satisfies $[r_{ijk}(\beta^\star)](a,b) \leq M^2$. The Hoeffding inequality yields that for any $(a,b)$ element of $I_{21}$,

\[
P\left(||I_{21}(a,b)|| > x\right) \leq 2 \cdot \exp\left(- \frac{k \cdot x^2}{8 \cdot M^2}\right),
\]

where $k = \lfloor n/3 \rfloor$. By the union bound inequality,

\[
||I_{21}||_{\infty} = O_p\left(M^2 \cdot \sqrt{\frac{\log d}{n}}\right).
\]

Similarly, $I_{22}$ is a mean-zero second order U-statistic with the kernel function $r_{ijj}(\beta^\star)$ satisfying $[r_{ijj}(\beta^\star)](a,b) \leq M^2$. By using the same arguments, we can show that

\[
||I_{22}||_{\infty} = O_p\left(M^2 \cdot \sqrt{\frac{\log d}{n}}\right).
\]
For $I_{23}$, note that $||h_{ij}||_x \leq M$, which implies that $||Eh_{ij}^{\otimes 2}||_x \leq M^2$. In addition, by the definition of $h_{ij|i}$ in (C.9), we can show that $||Eh_{ij}^{\otimes 2}||_x \leq M^2$. Hence, $||I_{23}||_x = \mathcal{O}_p(M^2)$.

Combining the error bounds for $I_{21}$, $I_{22}$ and $I_{23}$, we finally obtain

\begin{equation}
||I_2||_x = \mathcal{O}_p\left(M^2 \cdot \sqrt{\frac{\log d}{n}}\right).
\end{equation}

Combining the error bounds for $I_1$ and $I_2$ in (G.1) and (G.2), we can conclude the proof,

\begin{equation}
||\hat{\Sigma}(\hat{\beta}) - \Sigma||_x = \mathcal{O}_p\left(M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}}\right) + \mathcal{O}_p\left(M^2 \cdot \sqrt{\frac{\log d}{n}}\right) = \mathcal{O}_p\left(M^3 \cdot s \cdot \sqrt{\frac{\log d}{n}}\right).
\end{equation}

**G.2. Proof of Theorem D.1.** Before we present the proof of Theorem D.1, we start from the following Lemma.

**Lemma G.1.** Let $\Delta \in \mathbb{R}^d$ and $b = \max_{i<j} |(y_i - y_j)\Delta^T (x_i - x_j)|$, then

\begin{equation}
- \exp(-b) \nabla^2 \ell(\beta) \leq - \nabla^2 \ell(\beta + \Delta) \leq - \exp(b) \nabla^2 \ell(\beta),
\end{equation}

and

\begin{equation}
- \exp(-b) \Delta^T \nabla^2 \ell(\beta) \Delta \leq D(\beta + \Delta, \beta) \leq - \exp(b) \Delta^T \nabla^2 \ell(\beta) \Delta.
\end{equation}

**Proof.** The proof of this Lemma follows from that of Lemma A.4. Hence, we omit the details. \qed

Recall that $D(\hat{\beta}, \beta) = -(\hat{\beta} - \beta)^T (\nabla \ell(\hat{\beta}) - \nabla \ell(\beta))$ is the symmetrized Bregman divergence. By exploiting the KKT condition, we can show the following basic inequality.

**Lemma G.2.** Let $\hat{\Delta} = \hat{\beta} - \beta^*$ and $D(\hat{\beta}, \beta) = -(\hat{\beta} - \beta)^T (\nabla \ell(\hat{\beta}) - \nabla \ell(\beta))$. Then, we have

\begin{equation}
(\lambda - ||\nabla \ell(\beta^*)||_x) ||\hat{\Delta}_S||_1 \leq D(\hat{\beta}, \beta^*) + (\lambda - ||\nabla \ell(\beta^*)||_x) ||\hat{\Delta}_S||_1 \leq (\lambda + ||\nabla \ell(\beta^*)||_x) ||\hat{\Delta}_S||_1.
\end{equation}

Moreover, for any $\xi > 1$, $||\hat{\Delta}_S||_1 \leq \xi ||\hat{\Delta}_S||_1$, provided $||\nabla \ell(\beta^*)||_x \leq \lambda (\xi - 1)/(\xi + 1)$.\[\]
**Proof of Lemma** G.2. Since $-\ell(\beta)$ is convex, $D(\hat{\beta}, \beta) \geq 0$. Thus the first inequality holds. Denote $\hat{\Delta} = \hat{\beta} - \beta^*$. Note that

$$D(\hat{\beta}, \beta^*) = -\hat{\Delta}^T \{ \nabla \ell(\beta^*) + \hat{\Delta} \} - \nabla \ell(\beta^*)$$

$$= -\sum_{j \in S^c} \hat{\beta}_j \nabla_j \ell(\beta^*) + \sum_{j \in S} \hat{\Delta}_j \nabla_j \ell(\beta^*) + \hat{\Delta}^T \nabla \ell(\beta^*).$$

Furthermore, by the KKT condition, we have

$$D(\hat{\beta}, \beta^*) \leq -\sum_{j \in S^c} \lambda \hat{\beta}_j \text{sgn}(\hat{\beta}_j) + \sum_{j \in S} |\hat{\Delta}_j| \lambda + ||\hat{\Delta}||_1 ||\nabla \ell(\beta^*)||_{\infty}$$

$$= -\lambda ||\hat{\Delta}_{S^c}||_1 + \lambda ||\hat{\Delta}_S||_1 + ||\hat{\Delta}||_1 ||\nabla \ell(\beta^*)||_{\infty}$$

$$= \left( \lambda + ||\nabla \ell(\beta^*)||_{\infty} \right) ||\hat{\Delta}_S||_1 - (\lambda - ||\nabla \ell(\beta^*)||_{\infty}) ||\hat{\Delta}_{S^c}||_1.$$ 

This completes the proof. 

In the following, we start the proof of Theorem D.1. Let $\hat{\Delta} = \hat{\beta} - \beta^*$, $a = \hat{\Delta}/||\hat{\Delta}||_1$ and $x = ||\hat{\Delta}||_1$. By Lemma G.1, we get

(G.5)

$$D(\beta^* + xa, \beta^*) \geq -\exp(-b)x^2 a^T \nabla^2 \ell(\beta^*) a \geq -x^2 \exp(-Mx)a^T \nabla^2 \ell(\beta^*) a,$$

where

$$b = \max_{i<j} |(y_i - y_j)\hat{\Delta}^T(x_i - x_j)| \leq \max_{i<j} |(y_i - y_j)(x_{ik} - x_{jk})||\hat{\Delta}||_1 \leq Mx.$$ 

By the definition of the compatibility factor,

(G.6)

$$-a^T \nabla^2 \ell(\beta^*) a \geq \kappa^2 (\nabla^2 \ell(\beta^*), s)||a_S||_1^2/s.$$ 

By Lemma G.2, in the event $||\nabla \ell(\beta^*)||_{\infty} \leq \lambda(\xi - 1)/(\xi + 1)$, we have

(G.7)

$$D(\beta^* + xa, \beta^*) \leq \frac{2x\lambda}{\xi + 1} ||a_S||_1 - \frac{2x\lambda}{\xi + 1} ||a_{S^c}||_1$$

$$= 2x\lambda ||a_S||_1 - \frac{2x\lambda}{\xi + 1} \leq x\lambda(\xi + 1)||a_S||_1^2/2,$$

where the equality follows from $||a||_1 = 1$. Combining (G.5), (G.6) and (G.7), we derive

$$x \exp(-Mx) \leq \frac{2}{\lambda^2} \frac{\xi + 1}{(\xi^2 \ell(\beta^*), s)} \lambda s.$$
Note that by definition $M x \exp(-M x) \leq \tau$. Since $\eta$ is the smallest solution of $z \exp(-z) = \tau$, and $z \exp(-z) - \tau$ is an increasing function of $z$ for $z \leq 1$, we have $M x \leq \eta$. Thus

$$
\|\hat{\Delta}\|_1 = x \leq \eta M = \frac{\tau \exp(\eta)}{M} = \frac{(\xi + 1) \exp(\eta)}{2\kappa^2(\nabla^2 \ell(\beta^*), s)} \lambda s.
$$

This completes the proof of (D.2). To prove (D.3), by the definition of the restricted eigenvalue, we have

$$
- a^T \nabla^2 \ell(\beta^*) a \geq \text{RE}(\nabla^2 \ell(\beta^*), s) ||a||_2^2.
$$

Similar to (G.7), we have

$$
D(\beta^* + x a, \beta^*) \leq \frac{2x \xi \lambda}{1 + \xi} ||a_s||_1 \leq \frac{2x \xi \lambda}{1 + \xi} s^{1/2} ||a_s||_2 \leq \frac{2x \xi \lambda}{1 + \xi} s^{1/2} ||a||_2.
$$

Combining (G.5), (G.8) and (G.9), we derive

$$
x ||a||_2 \leq \frac{2\xi \exp(M x)}{(\xi + 1) \text{RE}(\nabla^2 \ell(\beta^*), s)} s^{1/2} \lambda.
$$

Note that $M x \leq \eta$. Then

$$
\|\hat{\Delta}\|_2 = x ||a||_2 \leq \frac{2\xi \exp(\eta)}{(\xi + 1) \text{RE}(\nabla^2 \ell(\beta^*), s)} s^{1/2} \lambda.
$$

This completes the proof of (D.3). Based on this result, we further combine (G.5) with (G.9),

$$
[\hat{\Delta}^T \nabla^2 \ell(\beta^*) \hat{\Delta}]^{1/2} \leq \frac{2\xi \exp(\eta)}{(\xi + 1) \text{RE}^{1/2}(\nabla^2 \ell(\beta^*), s)} s^{1/2} \lambda.
$$

To prove (D.4), by the definition of the weak cone invertibility factor, we have

$$
- a^T \nabla^2 \ell(\beta^*) a \geq \rho_q(\nabla^2 \ell(\beta^*), s) ||a_s||_1 ||a||_q / s^{1/q}.
$$

Similar to (G.7), we have

$$
D(\beta^* + x a, \beta^*) \leq \frac{2x \xi \lambda}{\xi + 1} ||a_s||_1 - \frac{2x \lambda}{\xi + 1} ||a_{s^c}||_1 \leq \frac{2x \xi \lambda}{\xi + 1} ||a_s||_1.
$$

Combining (G.5), (G.10) and (G.11), we derive

$$
x ||a||_q \leq \frac{2\xi \exp(M x)}{(\xi + 1) \rho_d(\nabla^2 \ell, s)} s^{1/q} \lambda.
$$
Since \( \|\hat{A}\|_q = x\|\alpha\|_q \) and \( Mx \leq \eta \), we obtain

\[
\|\hat{A}\|_q = x\|\alpha\|_q \leq \frac{2\xi \exp(\eta)}{(\xi + 1)\rho_d(\nabla^2 \ell, \varphi)^{1/2}} \lambda.
\]

This completes the proof of (D.4). By the KKT condition, if \( \hat{\beta}_j \neq 0 \), then

\[
\lambda \text{sign}(\hat{\beta}_j) = \nabla_j \ell(\hat{\beta}) = \nabla_j \ell(\beta^*) + \sum_{k=1}^d \nabla^2_{jk} \ell(\hat{\beta})(\hat{\beta} - \beta^*)_k,
\]

where \( \hat{\beta} \) is some intermediate value between \( \beta^* \) and \( \hat{\beta} \). Given event \( \mathcal{A}_2 \),

\[
\left| \sum_{k=1}^d \nabla^2_{jk} \ell(\hat{\beta})(\hat{\beta} - \beta^*)_k \right| \geq \lambda - \|\nabla \ell(\beta^*)\|_\infty = \frac{2}{\xi + 1} \lambda.
\]

Denote \( J(\hat{\beta}) = \{ j : \hat{\beta}_j \neq 0 \} \). Thus

\[
\frac{4 \lambda^2}{(\xi + 1)^2} \|\hat{\beta}\|_0 \leq \sum_{j \in J(\hat{\beta})} \left( \sum_{k=1}^d \nabla^2_{jk} \ell(\hat{\beta})(\hat{\beta} - \beta^*)_k \right)^2
\]

\[
\leq \|\nabla^2 \ell(\hat{\beta})(\hat{\beta} - \beta^*)\|_2
\]

\[
\leq \|\hat{\beta} - \beta^*\|_2 \lambda_{\text{max}}(-\nabla^2 \ell(\hat{\beta})),
\]

where \( \lambda_{\text{max}}(\nabla^2 \ell(\hat{\beta})) \) is the largest eigenvalue of \( \nabla^2 \ell(\hat{\beta}) \). By Lemma G.1 and the fact that \( Mx \leq \eta \),

\[-\nabla^2 \ell(\hat{\beta}) \leq -\exp(Mx)\nabla^2 \ell(\beta^*) \leq -\exp(\eta)\nabla^2 \ell(\beta^*).
\]

This implies that \( \lambda_{\text{max}}(-\nabla^2 \ell(\hat{\beta})) \leq \exp(\eta)\phi_{\text{max}} \). Together with (D.3), we find

\[
\|\hat{\beta}\|_0 \leq \frac{\exp(4\eta)\xi \phi_{\text{max}}}{\text{RE}^2(\nabla^2 \ell(\beta^*), \varphi)}.
\]

This completes the proof.

**G.3. Proof of Proposition D.1.** Denote \( F_{ij} = \{|y_i| \leq \eta\} \cap \{|y_j| \leq \eta\} \) and \( F'_{ij} = \{|\beta^T x_i| \leq R\} \cap \{|\beta^T x_j| \leq R\} \), where \( \eta \) and \( R \) are positive constants to be chosen later. We first apply a truncation argument for the Hessian matrix.

\[
-\nabla^2 \ell(\beta^*) \geq \frac{2}{n(n-1)} \sum_{i<j} \frac{R_{ij}(\beta^*)(y_i - y_j)^2(x_i - x_j)\otimes^2}{(1 + R_{ij}(\beta^*))^2} \cdot \mathbb{1}(F_{ij}) \cdot \mathbb{1}(F'_{ij})
\]

\[
\geq \frac{2 \cdot C_R}{n(n-1)} \sum_{i<j} (y_i - y_j)^2 \cdot (x_i - x_j)\otimes^2 \cdot \mathbb{1}(F_{ij}) \cdot \mathbb{1}(F'_{ij}),
\]
where $C_R = \exp(-4 \cdot R \cdot \eta) \cdot (1 + \exp(4 \cdot R \cdot \eta))^{-2}$. Consider the following U-statistic
\[
W = \frac{2 \cdot C_R}{n(n-1)} \sum_{i<j} (y_i - y_j)^2 \cdot (x_i - x_j)^{\otimes 2} \cdot \mathbb{1}(F_{ij}) \cdot \mathbb{1}(F'_{ij}).
\]

We first verify (D.6) holds. For any $v \in \mathbb{R}^d$, we get
\[
-v^T \nabla^2 \ell(\beta^*) v \geq v^T W v = v^T \mathbb{E}(W) v + v^T [W - \mathbb{E}(W)] v.
\]
By the Hölder inequality, we get
\[
|v^T W v - v^T \mathbb{E}(W) v| \leq \|v\|^2 \cdot \|W - \mathbb{E}(W)\|_{\infty},
\]
and it further implies that
\[
(G.13) \quad -v^T \nabla^2 \ell(\beta^*) v \geq v^T \mathbb{E}(W) v - \|v\|^2 \cdot \|W - \mathbb{E}(W)\|_{\infty}.
\]
Next, we establish the concentration of $W$ to its mean. Note that after the truncation argument, the kernel function of $W$ is bounded, i.e.,
\[
\|C_R \cdot (y_i - y_j)^2 \cdot (x_i - x_j)^{\otimes 2} \cdot \mathbb{1}(F_{ij})\|_{\infty} \leq 16 \cdot C_R \cdot m^2 \cdot \eta^2.
\]
The Hoeffding inequality can be applied to the centered U-statistic $W_{jk} - \mathbb{E}(W_{jk})$. For some constant $t > 0$ to be chosen, and any $1 \leq j, k \leq d$,
\[
P\left(|W_{jk} - \mathbb{E}(W_{jk})| \geq t\right) \leq 2 \cdot \exp\left(-\frac{k \cdot t^2}{2 \cdot C_R^2}\right).
\]
where $k = [n/2]$ and $C_R = 32 \cdot C_R \cdot m^2 \cdot \eta^2$. By the union bound inequality, (G.14)
\[
P\left(\|W - \mathbb{E}(W)\|_{\infty} \geq t\right) \leq \sum_{1 \leq j, k \leq d} P\left(|W_{jk} - \mathbb{E}(W_{jk})| \geq t\right) \leq 2 d^2 \exp\left(-\frac{k \cdot t^2}{2 \cdot C_R^2}\right).
\]
Taking $t = 4 \cdot C_R \cdot \sqrt{\log d/k}$, we obtain that $\|W - \mathbb{E}(W)\|_{\infty} \leq 4 \cdot C_R \cdot \sqrt{\log d/k}$, with probability at least $1 - 2d^{-6}$. As seen from (G.13), it remains to find a lower bound for $v^T \mathbb{E}(W) v$. In the following, we establish the lower bounds for three important generalized linear models, including linear regressions with Gaussian errors, logistic regressions and Poisson regressions.

**Linear model:** If $y$ follows from the linear model with $N(0, 1)$ error, with $\eta = 1$ under $F_{ij}$, we get
\[
\mathbb{E}\left[(y_i - y_j)^2 \cdot \mathbb{1}\{|y_i| < 1, |y_j| < 1\} \mid x_i, x_j\right] = \frac{1}{\sqrt{2\pi}} \cdot \int_{-1}^{1} \int_{-1}^{1} (y_i - y_j)^2 \cdot \exp\left[- \frac{(y_i - \beta^*^T x_i)^2 + (y_j - \beta^*^T x_j)^2}{2}\right] \cdot dy_i dy_j \\
\geq (G.15) \cdot \frac{1}{\sqrt{2\pi}} \cdot \int_{-1}^{1} \int_{-1}^{1} (y_i - y_j)^2 \cdot \exp\left[-(y_i^2 + y_j^2) - 2 \cdot R^2\right] \cdot dy_i dy_j.
\]
By (G.15), we have,
\[
\mathbf{v}^T \mathbb{E}(\mathbf{W}) \mathbf{v} = \mathbf{v}^T \mathbb{E}[\mathbb{E}(\mathbf{W} \mid \mathbf{x})] \mathbf{v} \geq C'_1 \cdot C'_R \cdot C'_R \cdot \mathbf{v}^T \mathbb{E}[(\mathbf{x}_i - \mathbf{x}_j)^{\otimes 2} \cdot 1(F'_{ij})] \mathbf{v}.
\]

Let \( F'_{ij} \) be the complement of \( F_{ij} \). The Cauchy inequality yields,
\[
\mathbf{v}^T \mathbb{E}[(\mathbf{x}_i - \mathbf{x}_j)^{\otimes 2} \cdot 1(F'_{ij})] \mathbf{v} \leq 4 \cdot \mathbf{v}^2 \cdot \mathbb{E}[(\mathbf{u}^T \mathbf{x}_i)^2 \cdot 1(F'_{ij})]
\]
\[
\leq 4 \cdot \mathbf{v}^2 \cdot \sqrt{\mathbb{E}((\mathbf{u}^T \mathbf{x}_i)^4 \cdot \mathbb{P}(F'_{ij}))}
\]
\[
\leq 16 \sqrt{2} \cdot \mathbf{v}^2 \cdot C_x^2 \cdot \sqrt{\mathbb{P}(|\mathbf{b}^T \mathbf{x}_i| > R)}
\]
\[
\leq C''_1 \cdot \mathbf{v}^2 \cdot C_x^2 \cdot \exp\left(-\frac{C''''_1 \cdot R^2}{C_R^2 \cdot C_x^2}\right),
\]

where \( C''_1 \) and \( C''''_1 \) are absolute positive constants. Now, we choose \( R \) such that
\[
C''_1 \cdot C_x^2 \cdot \exp\left(-\frac{C''''_1 \cdot R^2}{C_R^2 \cdot C_x^2}\right) \leq \lambda_{\min}(\Sigma_x).
\]

Thus, \( \mathbf{v}^T \mathbb{E}[(\mathbf{x}_i - \mathbf{x}_j)^{\otimes 2} \cdot 1(F'_{ij})] \mathbf{v} \leq \lambda_{\min}(\Sigma_x) \cdot \mathbf{v}^2 \), which implies that
\[
\mathbf{v}^T \mathbb{E}((\mathbf{x}_i - \mathbf{x}_j)^{\otimes 2} \cdot 1(F'_{ij})] \mathbf{v} \geq C''_1 C_R C'_R \left\{ \mathbf{v}^T \mathbb{E}(\mathbf{W}) \mathbf{v} - \mathbf{v}^T \mathbb{E}[(\mathbf{x}_i - \mathbf{x}_j)^{\otimes 2} \cdot 1(F'_{ij})] \mathbf{v} \right\}
\]
\[
\geq C''_1 C_R C'_R \cdot \lambda_{\min}(\Sigma_x) \cdot \mathbf{v}^2.
\]

By (G.13), (G.14) and (G.17), we finally obtain, with probability at least \( 1 - 2d^{-6} \),
\[
\mathbf{v}^T \nabla^2 \ell(\mathbf{b}^*) \mathbf{v} \geq \rho \cdot \mathbf{v}^2 - \tau \cdot \mathbf{v}_1^2 \cdot \frac{\log d}{k},
\]

where \( \rho = C_R \cdot C'_R \cdot \lambda_{\min}(\Sigma_x) \) and \( \tau = 4 \cdot C_R \).
**Logistic model:** If \( y \) given \( x \) follows from the logistic regression, one can take \( \eta = 1 \) in above proof, since \(|y| \leq 1\). In this case, (G.15) reduces to

\[
\mathbb{E}\left[(y_i - y_j)^2 \cdot 1\{|y_i| \leq 1, |y_j| \leq 1\} \mid x_i, x_j\right] = \mathbb{P}(y_i = 1 \mid x_i)\mathbb{P}(y_j = 0 \mid x_j) + \mathbb{P}(y_i = 0 \mid x_i)\mathbb{P}(y_j = 1 \mid x_j) 
\]

\[\text{(G.19)} = \frac{\exp(\beta^T x_i) + \exp(\beta^T x_j)}{[1 + \exp(\beta^T x_i)][1 + \exp(\beta^T x_j)]} \geq C_R'. \]

where

\[C_R' = \frac{2 \cdot \exp(-R)}{1 + \exp(R)^2}.\]

Hence, following the same arguments, we can establish (G.18) with \( \rho = C_R \cdot C_R' \cdot \lambda_{\min}(\Sigma_x) \) and \( \tau = 4 \cdot C_\eta \). Here, \( C_R' \) is redefined in (G.19).

**Poisson model:** If \( y \) given \( x \) follows from the Poisson regression, with \( \eta = 1 \), similarly, we can get

\[
\mathbb{E}\left[(y_i - y_j)^2 \cdot 1\{|y_i| \leq 1, |y_j| \leq 1\} \mid x_i, x_j\right] = \exp\left[\beta^T x_j - \exp(\beta^T x_i) - \exp(\beta^T x_j)\right] + \exp\left[y_i \beta^T x_i - \exp(\beta^T x_i) - \exp(\beta^T x_j)\right] \geq C_R', 
\]

where

\[C_R' = 2 \cdot \exp[-R - 2 \cdot \exp(R)].\]

Hence, following the same arguments, we can establish (G.18) with \( \rho = C_R \cdot C_R' \cdot \lambda_{\min}(\Sigma_x) \) and \( \tau = 4 \cdot C_\eta \). Here, \( C_R' \) is redefined in (G.20).

Next, we will verify the RE condition holds. For any \( v \in \mathbb{R}^d \) and \( \|v_S\|_1 \leq 3 \cdot \|v_S\|_1 \), by the Cauchy inequality, (G.13) further implies,

\[
-v^T \nabla^2 \ell(\beta^*) v \geq v^T \mathbb{E}(W)v - 16 \cdot \|v_S\|_1^2 \cdot \|W - \mathbb{E}(W)\|_\infty
\]

\[\text{(G.21)} \geq v^T \mathbb{E}(W)v - 16 \cdot s \cdot \|v\|_2^2 \cdot \|W - \mathbb{E}(W)\|_\infty. \]

Recall that, by (G.14), we obtain that \( \|W - \mathbb{E}(W)\|_\infty \leq 4 \cdot C_\eta \cdot \sqrt{\log d/n} \), with probability at least \( 1 - d^{-6} \). Similar to the proof of (G.18), after some algebra, it is easy to show that, for the Gaussian model, with probability at least \( 1 - 2d^{-6} \),

\[
-v^T \nabla^2 \ell(\beta^*) v \geq \rho' \cdot \|v\|_2^2,
\]

where

\[\rho' = C_R \cdot C_1' \cdot C_R' \cdot \lambda_{\min}(\Sigma_x) - 64 \cdot C_\eta \cdot s \cdot \sqrt{\log d/k}. \]

Here \( C_R' \) is defined in (G.16). Similarly, for the logistic model, (G.22) holds with \( C_1' = 1 \) and \( C_R' \) defined in (G.19). For the Poisson model, (G.22) holds with \( C_1' = 1 \) and \( C_R' \) defined in (G.20).
G.4. Proofs of Multiple Datasets Inference.

**Lemma G.3.** Denote $\hat{\Delta} = \hat{\beta}_H - \beta^*$ and $D_H(\beta_1, \beta) = (\beta - \beta)^T(\nabla \ell_H(\beta_1) - \nabla \ell_H(\beta))$. We have

$$
(\lambda_H - \|\nabla \ell_H(\beta^*)\|_{2,\infty}) \|\hat{\Delta}^S_H\|_{2,1} \leq D_H(\hat{\beta}_H, \beta^*) + (\lambda_H - \|\nabla \ell_H(\beta^*)\|_{2,\infty}) \|\hat{\Delta}^S_H\|_{2,1} \\
\leq (\lambda_H - \|\nabla \ell_H(\beta^*)\|_{2,\infty}) \|\hat{\Delta}^S_H\|_{2,1}.
$$

It implies that for any $\xi > 1$, $\|\hat{\Delta}^S_H\|_{2,1} \leq \xi \|\hat{\Delta}^S_H\|_{2,1}$, when $\|\nabla \ell_H(\beta^*)\|_{2,\infty} \leq \lambda(\xi - 1)/(\xi + 1)$.

**Proof of Lemma G.3.** Denote $\hat{\Delta} = \hat{\beta}_H - \beta^*$. Note that $\beta^j = 0$ if $j \in S_H$, and thus

$$
D_H(\hat{\beta}_H, \beta^*) = \hat{\Delta}^T \{\nabla \ell_H(\beta^* + \hat{\Delta}) - \nabla \ell_H(\beta^*)\} = \sum_{j \in S_H} \hat{\beta}_j^T \nabla H_j(\beta^* + \hat{\Delta}) + \sum_{j \in S_H} \hat{\Delta}^j \nabla H_j(\beta^* + \hat{\Delta}) - \hat{\Delta}^T \nabla \ell_H(\beta^*).
$$

Furthermore, by the KKT condition in (F.3) and Cauchy inequality, we have

$$
D_H(\hat{\beta}_H, \beta^*) \leq - \sum_{j \in S_H} \lambda_H \|\hat{\beta}_j\|_2 + \sum_{j \in S_H} \|\hat{\Delta}^j\|_2 \lambda_H + \sum_{j=1}^d \|\hat{\Delta}^j\|_2 \|\nabla \ell_H(\beta^*)\|_2 \\
\leq - \lambda_H \|\hat{\Delta}^S_H\|_{2,1} + \lambda_H \|\hat{\Delta}^S_H\|_1 + \|\hat{\Delta}\|_{2,1} \|\nabla \ell_H(\beta^*)\|_{2,\infty} \\
= (\lambda_H + \|\nabla \ell_H(\beta^*)\|_{2,\infty}) \|\hat{\Delta}^S_H\|_{2,1} - (\lambda_H - \|\nabla \ell_H(\beta^*)\|_{2,\infty}) \|\hat{\Delta}^S_H\|_{2,1}.
$$

This completes the proof. □

**Lemma G.4.** Let $\Delta \in \mathbb{R}^{d \times T}$ and $b = \max_i \max_{j < i} |(y_i(t) - y_j(t)) \Delta^T_i (x_i(t) - x_j(t))|$, then

(G.23) $\exp(-b) \nabla^2 \ell_H(\beta) \leq \nabla^2 \ell_H(\beta + \Delta) \leq \exp(b) \nabla^2 \ell_H(\beta),$

and

(G.24) $\exp(-b) \Delta^T \nabla^2 \ell_H(\beta) \Delta \leq D_H(\beta + \Delta, \beta) \leq \exp(b) \Delta^T \nabla^2 \ell_H(\beta) \Delta.$

**Proof of Lemma G.4.** Note that by Lemma G.1, for any $t = 1, ..., T$,

$$
\exp(-b_t) \nabla^2 \ell_t(\beta_t) \leq \nabla^2 \ell_t(\beta_t + \Delta_t) \leq \exp(b_t) \nabla^2 \ell_t(\beta_t),
$$

where $b_t = \max_{i < j} |(y_i(t) - y_j(t)) \Delta^T_i (x_i(t) - x_j(t))|$. Since $\nabla^2 \ell_H(\beta)$ is a block diagonal matrix with the $t$th block given by $\nabla^2 \ell_t(\beta_t)$ and by definition $b_t \leq b$, we obtain equation (G.23). (G.24) follows by (G.23) and the mean value theorem. □
Proof of Theorem F.1. Let $\Delta = \beta_H - \beta^*$, $a = \Delta/\|\Delta\|_{2,1}$ and $x = \|\Delta\|_{2,1}$. Note that
\[
\max_t \|\hat{\Delta}_t\|_1 \leq \sum_{j=1}^d \max_t |\hat{\Delta}_{ij}| \leq \sum_{j=1}^d \left(\sum_{t=1}^T \hat{\Delta}_{ij}^2\right)^{1/2} = \|\Delta\|_{2,1} = x.
\]
Hence,
\[
b = \max_{i \neq j} \max_t |(y_{i(t)} - y_{j(t)})\hat{\Delta}_t^T (x_{i(t)} - x_{j(t)})| \\
\leq \max_{i \neq j} \max_t \|(|y_{i(t)} - y_{j(t)}|)\|_{\infty} \max_t \|\hat{\Delta}_t\|_1 \leq Mx.
\]
By Lemma G.4, we get
\[
D_H(\beta^* + xa, \beta^*) \geq \exp(-b)x^2a^T\nabla^2\ell_H(\beta^*)a
\]
\(\geq x^2\exp(-Mx)a^T\nabla^2\ell_H(\beta^*)a,\)
\(\text{(G.25)}\)

By the definition of the compatibility factor,
\[
a^T\nabla^2\ell_H(\beta^*)a \geq \kappa_H^2(\nabla^2\ell_H(\beta^*), s_H)\|a + H\|_{2,1}^2s_H^{-1}.
\]
\(\text{(G.26)}\)

By Lemma G.3, provided $A_{2H}$ holds, we have
\[
D_H(\beta^* + xa, \beta^*) \leq \frac{2x\lambda_H}{\xi + 1} \|a + H\|_{2,1}^2s_H - \frac{2x\lambda_H}{\xi + 1} \|a + H\|_{2,1}^2s_H - \frac{2x\lambda_H}{\xi + 1}.
\]
\(\text{(G.27)}\)

By the Cauchy inequality, we obtain
\[
D_H(\beta^* + xa, \beta^*) \leq x\lambda_H(\xi + 1)\|a + H\|_{2,1}^2/2,
\]
\(\text{Combining (G.25), (G.26) and (G.27), we derive}\)
\[
x\exp(-Mx) \leq \frac{\xi + 1}{2\kappa_H^2(\nabla^2\ell_H(\beta^*), s_H)}\lambda_Hs_H = \tau \leq \frac{1}{e}.
\]
Since $\eta$ is the smallest solution of $z \exp(-z) = \tau$, and $f(z) = z \exp(-z) - \tau$ is an increasing function of $z$ for $z \leq 1$, we have $Mx \leq \eta$. Thus
\[
\|\hat{\Delta}\|_{2,1} = x \leq \frac{\eta}{M} = \frac{\tau \exp(\eta)}{M} = \frac{(\xi + 1) \exp(\eta)}{2\kappa_H^2(\nabla^2\ell_H(\beta^*), s_H)}\lambda_Hs_H.
\]
This completes the proof of (F.5).

To prove (F.6), by the definition of the restricted eigenvalue, we have
\[
a^T\nabla^2\ell_H(\beta^*)a \geq \text{RE}_H(\nabla^2\ell_H(\beta^*), s_H)\|a\|_{2,2}^2.
\]
\(\text{(G.28)}\)
Similar to (G.27), we have
\[
D_H(\beta^* + xa, \beta^*) \leq \frac{2x\xi\lambda_H}{1 + \xi} \|a^S_H\|_{2,1} \leq \frac{2x\xi\lambda_H}{1 + \xi} s_H^{1/2} \|a^S_H\|_{2,2} \leq \frac{2x\xi\lambda_H}{1 + \xi} s_H^{1/2} \|a\|_{2,2}.
\]
(G.29)
Combining (G.25), (G.28) and (G.29), we derive
\[
x\|a\|_{2,2} \leq \frac{2\xi \exp(Mx)}{(\xi + 1) \text{RE}_H(\nabla^2 \ell_H(\beta^*), s_H)} s_H^{1/2} \lambda_H.
\]
Note that \( Mx \leq \eta \). Then
\[
\|\tilde{\Delta}\|_{2,2} = x\|a\|_{2,2} \leq \frac{2\xi \exp(\eta)}{(\xi + 1) \text{RE}_H(\nabla^2 \ell_H(\beta^*), s_H)} s_H^{1/2} \lambda_H.
\]
This completes the proof of (F.6).
To prove (F.7), by the definition of the weak cone invertibility factor, we have
\[
a^T \nabla^2 \ell_H(\beta^*) a \geq \rho_H(\nabla^2 \ell_H(\beta^*), s_H) \|a^S_H\|_{\|a\|_{2,1}} \|a\|_{2,q}/s_H^{1/q}.
\]
Similar to (G.27), we have
\[
D_H(\beta^* + xa, \beta^*) \leq \frac{2x\xi\lambda_H}{\xi + 1} \|a^S_H\|_{2,1} - \frac{2x\lambda_H}{\xi + 1} \|a^S_H\|_{2,1} \leq \frac{2x\xi\lambda_H}{1 + \xi} s_H^{1/2} \|a^S_H\|_{2,1}.
\]
This yields,
\[
\|\tilde{\Delta}\|_{2,q} = x\|a\|_{2,q} \leq \frac{2\xi \exp(\eta)}{(\xi + 1) \rho_H(d(\nabla^2 \ell_H(\beta^*), s_H))} s_H^{1/2} \lambda_H.
\]
The proof is complete. By the KKT condition (F.3), if \( \tilde{\beta}_H^j \neq 0 \), then
\[
-\lambda_H \frac{\tilde{\beta}_H^j}{\|\tilde{\beta}_H^j\|_2} = \nabla_j \ell_H(\tilde{\beta}_H) = \nabla_j \ell_H(\beta^*) + \sum_{k=1}^d \nabla^2_{jk} \ell_H(\tilde{\beta})(\tilde{\beta}_H - \beta^*)^k,
\]
where \( \tilde{\beta} \) is some intermediate value between \( \beta^* \) and \( \tilde{\beta}_H \). Given event \( A_{H2} \),
\[
\| \sum_{k=1}^d \nabla^2_{jk} \ell_H(\tilde{\beta})(\tilde{\beta}_H - \beta^*)^k \|_2 \geq \lambda_H - \| \nabla \ell_H(\beta^*) \|_2, = \frac{2}{\xi + 1} \lambda_H.
\]
Denote $J(\hat{\beta}_H) = \{ j : \hat{\beta}_j \neq 0 \}$. Thus
\[
\frac{4\lambda_H^2}{(\xi + 1)^2} |J(\hat{\beta}_H)| \leq \sum_{j \in J(\hat{\beta}_H)} \| \sum_{k=1}^{d} \nabla_H^2 \ell_H(\hat{\beta})(\hat{\beta}_H - \beta^*)^k \|_2^2 \\
\leq \| \nabla_H^2 \ell_H(\hat{\beta})(\hat{\beta}_H - \beta^*) \|_2^2 \\
\leq \| \hat{\beta}_H - \beta^* \|_2^2 \lambda_{\text{max}}^2(\nabla_H^2 \ell_H(\hat{\beta})).
\]

By Lemma G.4 and the fact that $M \leq \eta$,
\[
\nabla_H^2 \ell_H(\hat{\beta}) \leq \exp(M \xi) \nabla_H^2 \ell_H(\beta^*) \leq \exp(\eta) \nabla_H^2 \ell_H(\beta^*).
\]

This implies that $\lambda_{\text{max}}(\nabla_H^2 \ell_H(\hat{\beta})) \leq \exp(\eta) \phi_{\text{max}}$, and thus
\[
|J(\hat{\beta}_H)| \leq \frac{\exp(4\eta) \phi_{\text{max}}^2}{R \exp(\nabla_H^2 \ell_H(\beta^*), s_H)}.
\]

This completes the proof.

**Lemma G.5.** Let $Z_1, ..., Z_n$ be $d$-dimensional independent random vectors and $Z_{ij}$ be the $j$th component of $Z_i$. Then,
\[
E\left( \max_{1 \leq j \leq d} \left| \sum_{i=1}^{n} (Z_{ij} - E[Z_{ij}]) \right| \right) \leq (8 \log(2d))^{1/2} E\left( \left[ \max_{1 \leq j \leq d} \left( \sum_{i=1}^{n} Z_{ij}^2 \right) \right]^{1/2} \right).
\]

**Proof of Lemma G.5.** Define the random variable $W_j = |\sum_{i=1}^{n} Z_{ij} \epsilon_i|$, where $(\epsilon_1, ..., \epsilon_n)$ is a sequence of i.i.d Rademacher random variables independent of $Z = (Z_1, ..., Z_n)$. Let $E_Z$ denote the conditional expectation given $Z$. For any $t > 0$, by Jensen’s inequality,
\[
E_Z(\max_{1 \leq j \leq d} W_j) \leq t \log \left\{ E_Z \exp \left( \max_{1 \leq j \leq d} W_j/t \right) \right\} \leq t \log \left\{ \sum_{j=1}^{d} E_Z \exp(W_j/t) \right\}.
\]

Using Hoeffding’s inequality, $E_Z \exp(W_j/t) \leq 2 \exp(\sum_{i=1}^{n} Z_{ij}^2/(2t^2))$, which yields,
\[
\sum_{j=1}^{d} E_Z \exp(W_j/t) \leq 2d \max_{1 \leq j \leq d} \exp \left( \sum_{i=1}^{n} Z_{ij}^2/(2t^2) \right).
\]

Thus,
\[
E_Z(\max_{1 \leq j \leq d} W_j) \leq t \left\{ \log(2d) + \max_{1 \leq j \leq d} \left( \sum_{i=1}^{n} Z_{ij}^2/(2t^2) \right) \right\}.
\]
With $t = \sqrt{\max_{1 \leq j \leq d} \sum_{i=1}^{n} Z_{ij}^2 / (2 \log(2d))}$, we obtain
\[(G.30)\]
\[
\mathbb{E}_{Z}( \max_{1 \leq j \leq d} W_j ) \leq \left[ 2 \log(2d) \right]^{1/2} \mathbb{E} \left( \left[ \max_{1 \leq j \leq d} \sum_{i=1}^{n} Z_{ij}^2 \right]^{1/2} \right).
\]
By symmetrization, we get
\[(G.31)\]
\[
\mathbb{E} \left( \max_{1 \leq j \leq d} \left| \sum_{i=1}^{n} (Z_{ij} - \mathbb{E} Z_{ij}) \right| \right) \leq 2 \mathbb{E}_{Z}( \max_{1 \leq j \leq d} W_j ).
\]
We complete the proof by combining (G.30) and (G.31).

**Proof of Lemma F.2.** Note that $x^M \leq \log^M (e^x + e^{M-1}) - 1$. For any $t > 0$, by Jensen’s inequality,
\[
\mathbb{E} \left( \max_{1 \leq j \leq d} |U_j|^M \right) \leq t^M \mathbb{E} \log^M \left\{ \exp \left( \max_{1 \leq j \leq d} |U_j|/t \right) + \exp(M - 1) - 1 \right\}
\leq t^M \log^M \left\{ \mathbb{E} \exp \left( \max_{1 \leq j \leq d} |U_j|/t \right) + \exp(M - 1) - 1 \right\}
\leq t^M \log^M \left\{ \sum_{j=1}^{d} \mathbb{E} \exp \left( |U_j|/t \right) + \exp(M - 1) - 1 \right\}.
\]
Consider the following representation of $U$,
\[
U = \frac{1}{n!} \sum_{i_1,...,i_n} v(X_{i_1},...,X_{i_n}),
\]
where the summation is over all $n!$ permutations of $\{1,...,n\}$, and
\[
v(X_{i_1},...,X_{i_n}) = \frac{1}{k} \sum_{s=1}^{k} Y_s, \quad \text{where} \quad Y_s = u(X_{sm-m+1},...,X_{sm}).
\]
Note that $v(X_{i_1},...,X_{i_n})$ is an average of $k$ independent random variables. Similar to the proof of Lemma A.3, by Jensen’s inequality and independence of $Y_j$, we obtain
\[
\mathbb{E} \exp \left( |U_j|/t \right) \leq \frac{2}{n!} \sum \mathbb{E} \exp \left( \sum_{s=1}^{k} \frac{Y_{js}}{kt} \right) \leq \frac{2}{n!} \sum \prod_{s=1}^{k} \mathbb{E} \exp \left( \frac{Y_{js}}{kt} \right),
\]
where the summation is over all $n!$ permutations of $\{1,...,n\}$. By (C.8), for $t \geq \frac{2L_1}{L_2^2 k}$,
\[
\mathbb{E} \exp \frac{Y_{js}}{kt} \leq \exp \left\{ 2 \left( \frac{L_1}{L_2} \right)^2 \frac{1}{k^2 t^2} \right\}.
\]
This implies that

\[ \mathbb{E} \exp \left( \frac{|U_j|}{t} \right) \leq 2 \exp \left\{ 2 \left( \frac{L_1}{L_2} \right)^2 \frac{1}{kt^2} \right\}. \tag{G.33} \]

Using (G.32) and (G.33) and \(2dx + \exp(M - 1) - 1 \leq c_M dx\), we have

\[
\mathbb{E}(\max_{1 \leq j \leq d} |U_j|^M) \leq t^M \log^M \left\{ 2d \exp \left\{ 2 \left( \frac{L_1}{L_2} \right)^2 \frac{1}{kt^2} \right\} + \exp(M - 1) - 1 \right\}
\leq t^M \log^M \left\{ c_M d \exp \left\{ 2 \left( \frac{L_1}{L_2} \right)^2 \frac{1}{kt^2} \right\} \right\}
= t^M \left\{ \log(cMd) + 2 \left( \frac{L_1}{L_2} \right)^2 \frac{1}{kt^2} \right\}^M.
\]

Since \(k^{-1} \log(cMd) \leq 1/2\), we can take \(t = \sqrt{\frac{2L_1^2}{L^2_k \log(CMd)}}\), which satisfies \(t \geq \frac{2L_1}{L^2_k}\). This yields,

\[
\mathbb{E}(\max_{1 \leq j \leq d} |U_j|^M) \leq 2^{3M/2} \left( \frac{L_1}{L_2} \right)^M \left( \frac{\log(cMd)}{k} \right)^{M/2}.
\]

\[ \square \]

**Proof of Lemma F.1.** Denote

\[
B_{tkij} = -\frac{R_{ij}(\beta^*)(y_{i(t)} - y_{j(t)})(x_{ik(t)} - x_{jk(t)})}{1 + R_{ij}(\beta^*)},
\]

\[
D_{tk} = \left( \frac{n_t}{2} \right) \sum_{i < j} B_{tkij}, \quad A_{tk} = D_{tk}^2, \quad \text{and} \quad W_{tk} = A_{tk} - \mathbb{E}(A_{tk}).
\]

For any \(t > 0\), by Markov inequality,

\[
\mathbb{P}\left( \|\nabla \ell_H(\beta^*)\|_{2, \infty} > t \right) = \mathbb{P}\left( \max_{1 \leq k \leq d} \left( \sum_{t=1}^T A_{tk} \right)^{1/2} > t \right)
\leq \mathbb{P}\left( \max_{1 \leq k \leq d} \sum_{t=1}^T W_{tk} > t^2 - \max_{1 \leq k \leq d} \sum_{t=1}^T \mathbb{E}(A_{tk}) \right)
\leq \left( t^2 - \max_{1 \leq k \leq d} \sum_{t=1}^T \mathbb{E}(A_{tk}) \right)^{-1} \mathbb{E}\left( \max_{1 \leq k \leq d} \left| \sum_{t=1}^T W_{tk} \right| \right).
\]
We first consider $\mathbb{E}(A_{tk})$. Note that

$$(G.34) \quad \mathbb{E}(A_{tk}) = \frac{4}{n_t^2(n_t - 1)^2} \sum_{i \neq j} \sum_{l < m} \mathbb{E}(B_{tkij}B_{tklm}).$$

By Assumption 4.1,

$$(G.35) \quad \mathbb{E}(y_i - y_j)^2 = \mathbb{E}y_i^2 + \mathbb{E}y_j^2 \leq \bar{C}, \quad \text{where} \quad \bar{C} = 2 \int_0^\infty C' \exp(-Cx^{1/2}) dx.$$

There exist three cases in (G.34). When $i = l$ and $j = m$, by Assumption 4.1 and (G.35) we obtain $\mathbb{E}(B_{tkij}B_{tklm}) \leq 4m^2\bar{C}$. When either $i = l$, $j = m$, $i = m$ or $j = l$ is true, $\mathbb{E}(B_{tkij}B_{tklm}) \leq 2m^2\bar{C}$. Finally, when none of $i$, $j$, $l$ and $m$ are identical, we have $\mathbb{E}(B_{tkij}B_{tklm}) = \mathbb{E}(B_{tkij})\mathbb{E}(B_{tklm}) = 0$. Thus, for any $n > 1$, (G.34) can be bounded by

$$(G.36) \quad \mathbb{E}(A_{tk}) \leq \frac{4}{n_t^2(n_t - 1)^2} \left( \frac{n_t(n_t - 1)}{2} 4m^2\bar{C} + 8n^3m^2\bar{C} \right) \leq \frac{160m^2\bar{C}}{n}.$$

By Lemma G.5, Jensen’s inequality and independence of $A_{1k}, \ldots, A_{Tk}$,

$$\mathbb{E}\left( \max_{1 \leq k \leq d} \left| \sum_{t=1}^T W_{tk} \right| \right) \leq [8 \log(2d)]^{1/2} \mathbb{E}\left( \left( \max_{1 \leq k \leq d} \sum_{t=1}^T A_{tk}^2 \right)^{1/2} \right) \leq [8 \log(2d)]^{1/2} \left( \mathbb{E}\left( \left( \sum_{t=1}^T \max_{1 \leq k \leq d} A_{tk}^2 \right)^2 \right) \right)^{1/2}.$$

Recall that $A_{tk} = D_{tk}^2$ and $D_{tk}$ is a mean zero second order U-statistic. To control $\mathbb{E}\max_{1 \leq k \leq d} A_{tk}^2$, we apply Lemma F.2 with $m = 2$, $k = \lfloor n_t/2 \rfloor$, $M = 4$, $c_4 = 12$, $L_1 = 2C'$ and $L_2 = C/(4m)$,

$$\mathbb{E}\left( \max_{1 \leq k \leq d} A_{tk}^2 \right) \leq 2^6 \left( \frac{8C'm}{C} \right) \left( \frac{\log(12d)}{\lfloor n_t/2 \rfloor} \right)^2.$$

Thus,

$$(G.37) \quad \mathbb{E}\left( \max_{1 \leq k \leq d} \left| \sum_{t=1}^T W_{tk} \right| \right) \leq \sqrt{\frac{8T \log(2d)}{n}} \frac{2^5 \log(12d)}{n} \left( \frac{8C'm}{C} \right)^2.$$
Combining (G.36) with (G.37), we have

\[
P\left( \| \nabla \ell_H(\beta^*) \|_{2,\infty} > t \right) \leq \left( t^2 - \frac{160m^2\bar{C}}{n} T \right)^{-1} \sqrt{8T \log(2d)} \times 2^5 \log(12d) \left( \frac{8C''m}{C} \right)^2.
\]

We complete the proof by taking

\[
t = \frac{160^{1/2}m\bar{C}^{1/2}T^{1/2}}{n^{1/2}} + \frac{T^{1/4} \log(2d)^{3/4+\delta}}{n^{1/2}} \frac{32 \sqrt{2C'm}}{C}.
\]

This finishes the proof. \hfill \Box

**Lemma G.6.** Assume that both \( m = \max_{1 \leq t \leq T} \max_{i,j} |x_{ij(t)}| \) and \( R = \max_{1 \leq t \leq T} \max_i |\beta_t^* x_{t(i)}| \) are bounded. Assume that \( y(t) \) given \( x_t(t) \) satisfies one of the following models,

1. Gaussian linear regression, \( y(t) = \beta_t^* x_t(t) + \epsilon \), with \( \epsilon \sim N(0, 1) \),
2. 0-1 Logistic regression, \( \mathbb{P}(y(t) = 0 \mid x_t(t)) = (1 + \exp(\beta_t^* x_t(t)))^{-1} \),
3. Poisson regression, \( \mathbb{P}(y(t) \mid x_t(t)) = \exp(y(t)\beta_t^* x_t(t) - \exp(\beta_t^* x_t(t)))/y(t)! \).

Denote the covariance matrix of \( x_t(t) \) to be \( \Sigma_{xt} = \text{Cov}(x_t(t)) \). Then there exist constants \( C, C', C'' > 0 \) such that

\[
\kappa^2_H(\nabla^2 \ell_H(\beta^*), s_H) \geq C \min_{1 \leq t \leq T} \lambda_{\min}(\Sigma_{xt}),
\]

\[
RE_H(\nabla^2 \ell_H(\beta^*), s_H) \geq C \min_{1 \leq t \leq T} \lambda_{\min}(\Sigma_{xt}),
\]

\[
\rho_H(\nabla^2 \ell_H(\beta^*), s_H) \geq C \min_{1 \leq t \leq T} \lambda_{\min}(\Sigma_{xt}),
\]

with probability at least \( 1 - C'dT^2 \exp(-C''nS_H^2T^{-2} \{ \min_{1 \leq t \leq T} \lambda_{\min}(\Sigma_{xt}) \}^2) \).

**Proof of Lemma G.6.** The proof is similar to that of Proposition D.1 and is omitted for simplicity. \hfill \Box

**Appendix H: Inference on Multi-Dimensional Parameters**

In this section, we consider the case that the parameter of interest \( \alpha \) is \( K \)-dimensional. Here, \( K \) can be greater than 1 but is fixed not increasing with \( n \). Following the similar argument to the univariate case, we define the directional likelihood function for \( \alpha \) as

\[
\hat{\ell}(\alpha) = \ell(\alpha, \hat{\gamma} + \hat{\mathbf{W}}(\hat{\alpha} - \alpha)),
\]
where \( \hat{\beta} : (\hat{\alpha}, \hat{\gamma}) \) is a first-stage regularized estimator for \( \beta^* \), and \( \hat{W} \) is an estimator for
\[
W^* = H_{\alpha\gamma}(H_{\gamma\gamma})^{-1} \in \mathbb{R}^{K \times (d-K)}.
\]
In particular, \( \hat{W} = (\hat{W}_1, \ldots, \hat{W}_K) \) is given by the following Lasso type estimator
\[
\hat{W}_k = \arg \max_{w \in \mathbb{R}^{d-K}} \left\{ \frac{1}{2} w^T \nabla^2_{\gamma \gamma} \ell(\hat{\beta}) w - w^T \nabla_{\gamma \alpha_k} \ell(\hat{\beta}) - \lambda_1 \| w \|_1 \right\},
\]
for \( 1 \leq k \leq K \). In addition, we define the maximum directional likelihood estimator as
\[
\hat{\alpha}^P = \arg \max_{\alpha \in \mathbb{R}^K} \ell(\alpha).
\]
To test the null hypothesis \( H_0 : \alpha^* = \alpha_0 \), we define the maximum directional likelihood ratio test (DLRT) statistic as
\[
\Lambda_n = 2n \{ \hat{\ell}(\hat{\alpha}^P) - \hat{\ell}(\alpha_0) \}.
\]
Similar to Theorem 4.1, we can prove
\[
n^{1/2} (\hat{\alpha}^P - \alpha^*) \sim \text{MVN} (0, 4 \cdot H_{\alpha\gamma}^{-1} \sigma^2 H_{\alpha\gamma}^{-1}),
\]
where \( \sigma^2 = \Sigma_{\alpha\alpha} - 2W^T \Sigma_{\gamma\gamma} W + W^T \Sigma_{\gamma\gamma} W \), \( H_{\alpha\gamma} = H_{\alpha\alpha} - H_{\alpha\gamma} H_{\gamma\gamma}^{-1} H_{\gamma\alpha} \) and \( \Sigma_{\alpha\alpha} \), \( \Sigma_{\gamma\gamma} \) and \( \Sigma_{\gamma\gamma} \) are corresponding partitions of \( \Sigma \). Recall that \( \sigma^2 \) and \( H_{\alpha\gamma} \) can be similarly estimated by \( \hat{\sigma}^2 \) and \( \hat{H}_{\alpha\gamma} \). Therefore, a confidence region for \( \alpha^* \) with \((1 - \xi)\) coverage probability is given by
\[
\text{CR}_\xi = \left\{ \alpha \in \mathbb{R}^K : 4^{-1} n (\alpha - \hat{\alpha}^P)^T \hat{H}_{\alpha\gamma} \hat{\sigma}^{-2} \hat{H}_{\alpha\gamma} (\alpha - \hat{\alpha}^P) \leq \chi^2_{K, \xi} \right\},
\]
where \( \chi^2_{K, \xi} \) is the \((1 - \xi)\)-th quantile of a \( \chi^2_K \) random variable.

In addition, to test the null hypothesis \( H_0 : \alpha^* = \alpha_0 \), we can show that under the null hypothesis, the maximum directional likelihood ratio test statistic \( \Lambda_n \) satisfies for each \( t \in \mathbb{R} \)
\[
\lim_{n \to \infty} \left| \mathbb{P}(\Lambda_n \leq t) - \mathbb{P}(Z^T H_{\alpha\gamma}^{-1} Z \leq t) \right| = 0,
\]
where \( Z \sim \text{MVN} (0, 4 \sigma^2) \). This result establishes the limiting distribution of \( \Lambda_n \) under the null hypothesis. It can be used to calculate p-values, once \( \sigma^2 \) and \( H_{\alpha\gamma} \) are estimated.
APPENDIX I: ADDITIONAL NUMERICAL RESULTS

In this section we present additional simulation results. The setup is similar to that in Section 5 of the main text, but we consider higher dimensional settings with $d = 500$ and $d = 1000$. The number of repetitions is 400. We also examine the Poisson regression model, in which $Y_i$ are drawn i.i.d. from a Poisson distribution with mean parameter $\lambda_i = e^{X_i^T \beta}$. The numerical results for $d = 500$ is shown in Table 1. In this table, we also compare two different methods for choosing the tuning parameters. In the first method, the tuning parameters are chosen by the theoretical levels of $\lambda = 4\sqrt{\log d/n}$ and $\lambda_1 = 4 \log n \sqrt{\log d/n}$. In the second method, they are chosen by cross validation as discussed in Section 5. The results for $d = 1000$ is shown in Table 2.

It can be seen that the type I errors are close to their theoretical values in all settings. In particular, our tests are valid under the high-dimensional Poisson regression, which has not been studied or tested anywhere in the literature. Moreover, it can be seen that choosing theoretical values for the tuning parameters have similar effects as employing cross validation.

We report the computational time of the methods considered above. Our directional likelihood ratio test on average takes 14.879 seconds, while the de-biased and de-sparsified lasso method takes 0.499 and 0.681 seconds. Our method is slower as we are essentially working with a $n(n-1)/2 \times d$ dimensional regression problem. The computational speeds are reported based on simulations run on Mac X Yosemite with 2.7GHZ Intel Core i5.
