In-beam Spectroscopy of ^{68}Se . S.M. FISCHER, D.P. BALAMUTH, P. HAUSLADEN, University of Pennsylvania, C.J. LISTER, D.J. BLUMENTHAL, J. SCHWARTZ, Argonne National Laboratory, M.J. LEDDY, University of Manchester, D.G. SARANTITES, M. DEVLIN, Washington University. — Nuclei with $N \approx Z$ in the $A=70$ mass region exhibit rapid changes in shape with the addition or subtraction of one or two particles; shape coexistence has been demonstrated in slightly lighter systems. Experimental investigation of these $N=Z$ nuclei has proven to be quite difficult, principally due to very low cross sections for relevant fusion-evaporation reactions. To date only three transitions have been reported ¹ in ^{68}Se . In the present work, ^{68}Se was produced via the $^{40}\text{Ca}(^{36}\text{Ar}, 2\alpha)$ reaction at a beam energy of 140 MeV. The Gammasphere and Microball arrays were used to detect γ -rays of fold 3 and higher in coincidence with evaporated charged particles. Doppler corrections were applied on an event-by-event basis to γ -rays in coincidence with 2 α particles, and a careful subtraction of feedthrough channels was performed. Two previously identified transitions in ^{68}Se have been confirmed and at least seven new transitions have been observed. The proposed level scheme, based on coincidence relationships and γ -ray angular distributions, will be discussed.
