Tectonic geomorphology and earthquake geology of the 1857 reach of the San Andreas Fault: a new look from Airborne Laser Swath Mapping

J. R. Arrowsmith¹, B. Campbell², C. Crosby¹, D. Raleigh³ (¹School of Earth and Space Exploration, Arizona State University; ²Elizabeth City State University, Elizabeth City, North Carolina; ³Ohio State University)

Important information about paleoearthquakes is recorded in the meter-scale tectonic geomorphology of fault zones. Such information is available from both the records of offset and from paleoseismic sites which are better understood with enhanced knowledge of geomorphic context. The B4 airborne laser swath mapping dataset of the topography along the San Andreas Fault (SAF) zone has enabled a spectacular new look at the 10s-of-meter scale tectonic geomorphology and is a powerful complement to field survey. We explored the applicability of these data to several aspects of the tectonic geomorphology of the SAF. This exploration has included significant data-processing assessment with application to fault trace mapping and offset stream channel study. We analyzed the point cloud itself, as well as several methods of filtering and gridding the data to produce digital elevation models (DEMs). Shot densities are typically 5-10 and as high as 33 per square meter with swath overlap. 1 m resolution DEMs show the topography well with few artifacts. Swath to swath position errors induce decimeter errors in adjacent scan lines from different swaths. The scan lines can be separated by 30-100 cm, so with DEM resolutions lower than that separation (e.g., 25 cm), decimeter high swath normal ridges ("corduroy") are notable artifacts. We have interpolated the data using kriging and spline methods and use local binning of the maximum, mean, and minimum elevation within a specified search radius (usually the DEM resolution) using the GEON LiDAR Workflow. The minimum method removes some low vegetation (sagebrush) in the data that obscures landforms. The data are unprecedented in their power to quantitatively depict the tectonic landforms along the SAF. We closely examined several reaches of the fault in the Carrizo Plain, including that part covered by our pilot B4 dataset. We compared our estimates of 1857 and earlier offset from the field and from the B4-derived DEMs (where available) to the estimates from Sieh, 1978. We found that combinations of field and virtual examination provided our most confident estimates. In addition, a quantitative offset estimation using SAF spanning and parallel profiles was possible in places with higher quality obvious offsets. Broad (>several m) and shallow channels (<1 m) were difficult to confidently match with this semi-automated approach. Topographic profile matching as we employ here assumes that the channel elements can be projected to a SAF-parallel plane and there offsets are thus measured. It does not allow for any initial irregularities or non-orthogonality to the SAF in the landform elements. We are working on methods to improve this and fit surfaces to each side’s geomorphology that can be projected appropriately and the offset more carefully reconstructed with uncertainty estimated.

This project was developed with support from EAR-0225543 (GEON) and EAR-0409745 (Collaborative Research: Multi-cycle Rupture History of the San Andreas Fault in the Carrizo Plain; Arrowsmith CoPI)
Figure 1. High resolution B4 topography along the San Andreas Fault in the northwestern Carrizo Plain. Strip at right is a 1 m DEM from B4 data computed using Geon LiDAR Workflow. It dramatically shows the tectonic geomorphology along the fault zone. Red lines are active fault traces. Yellow numbers indicate the offset locations compiled from Sieh, 1978. The Bidart site is bounded by channels 32 and 33. Detailed map below shows the topographic slope computed from the 1 m B4 DEM semi transparent over the hillshade at the Bidart site. The subtle slope changes indicate the SAF zone which offsets the two channels. Polygons illustrate paleoseismic trenches previously (white) and recently excavated (blue).
Offset at SE end of Bidart site (NW of T2) was measured as 9.6±1.4 m by Sieh and 7-8 m by Grant and Sieh, 1994. Alternative interpretations are as much as 13.5 m. T2 offset in B4 data has thalweg offset of 7.1 m and a cross correlation offset of 7.7 m. 25 cm resolution spline-derived DEMs are from B4 dataset.

New offset channel discovered with cursory review of 0.5 m B4 DEM. This 0.5 m deep and ~10 m channel is offset 7 m. 25 cm resolution spline-derived DEMs are from B4 dataset.

Figure 2. Offset stream channel analysis at the Bidart paleoseismic site along the San Andreas Fault (see Figure 1 for location). These 25 cm DEMs were computed using the spline interpolation module in the GEON LiDAR Workflow.
